and bronchitis. The average cardiac is much steadier and better physically at work in a well ventilated factory than exposed outdoors to a New York winter.

A great many inquiries have come to the New York State Rehabilitation Bureau as to suitable occupations for cardiacs. It is difficult to state that one trade is wholly suitable or unsuitable for a particular group of the handicapped, because one must be flexible if one hopes to place people in work congenial to their tastes. The lists of occupations given in Tables I and II are offered therefore only for what suggestive value they may have.

TABLE I.—OCCUPATIONS FOR CARDIACS.

For Men and Boys Industry—Skilled	Process	Remarks.
Jewelry	All processes Jewelry design.	This work has proved to be excellent as it is light and varied.
Watch and clock....	Repairing	The advantage of this work is that a skilled man can work at it part time in his home, if necessary.
Instrument making..	Assembly, etc.,	Much of this work is seated.
Electrical manufac- ture.	Assembly, soldering, etc.	The cardiac who wants to be a radio operator may have to be satisfied in assembling radio parts. Radio work itself is very unsuitable.
Celluloid novelties...	Engraving, jig saw... and assembly.	This work often is done with firms making spectacles.
Diamond	Polishing	
Architecture	Draughting	
Mechanical engineer- ing.	Draughting	
Automobile	Vulcanizing	This work seldom suitable for a IIb case.
Barber	Barber	Not suitable for a cardiac who cannot stand for long periods or work quickly.
Pocket book	Pasting and operating	Not suitable for neurotic cardiacs because of excessive speed.
Garment and fur....	Operating, finishing, etc.	
Clerical	Bookkeeping, stenog- raphy, accountancy.	
Photography	Retouching	Dark room conditions would not be suitable to many cardiacs.
Printing	Proof reading and copy-holding.	Home work might be possible.
Lithography	Lettering, poster, ar- tist, stone artist, and photographer.	
Steel engraving....	Painting faces.	
Dolls	Grinding, rubber turn- ing, etc.	Most of this work is seated.
Fountain pen....	Glueing, assembly, etc.	
Piano actions....	Covering, machine work.	
Buttons		
Unskilled and Semi- skilled:		
Restaurant	Cashier and checker.	
Shipping	Checker.	
Buildings	Elevator operators.	
Apartment house ..	Switchboard	Provided board is not too heavy and there is not too much excitement.
Construction	Watchman	Provided stair climbing is limited
News-stand	News-stand	Provided there is not too much exposure to inclement weather.
Hotels, clubs, etc.,	Doormen	
Theater	Ticket taker.	

Temperament often limits the cardiac as much as his physical condition does. The placement worker must be very cautious of the things cripples state they cannot do, unless their statements are corroborated by a physician. For instance, many cardiacs claim they cannot work if there is the least dust in the air. Where there is an asthmatic complication, it is of course inadvisable to place a cardiac where there is anything which is apt to make him cough, but the majority of cardiacs will not be injured by the atmosphere of most well kept factories. Some cardiacs complain of their sen-

sitiveness to smell. This is usually mental. Such prejudices often have to be accepted, however, although they have no physical basis. Sensitiveness to foreign proteins causing asthma and hay fever may, however, be the cause of serious complications in a cardiac and still further limit the available occupations.

Experience seems to show that most cardiacs are inert and lacking in initiative. They seldom suggest what work they want to do themselves, but it must be suggested to them. It is unusual to come across a cardiac who wants to do work which exceeds his strength. Cardiacs are apt to worry about themselves and to

become neurasthenic. The quicker a cardiac can be readjusted to work the less apt he is to become depressed. Therefore, if the cardiac is to take training, it is usually preferable to give him a brief rather than a prolonged course of training. For the same reason, wherever possible, a cardiac should remain at his old trade and do that part which does not aggravate his physical condition. The less readjustment he has to make, the less likely he is to become despondent. Many cardiacs cannot remain at their old

trades, but wherever it is possible it should be encouraged.

It will be of interest to discuss under fictitious names some of the types of neurasthenic cardiacs who have come to the State Bureau of Rehabilitation. Callan, age 26, was sent by a doctor who stated the man should be able to work at least eight hours a day at a sedentary job. Whenever such a position was secured for him, however, he became so excited that he overtaxed his strength and had to give up his job. Obberman, a IIa cardiac, left each job offered him because he said "it got on his nerves." He was so lacking in cooperation and

so irregular at work that he was unplaceable. Mrs. Jones, age 27, was an ironer in a laundry. The doctor stated such work was unsuitable and her condition would improve under the proper conditions. She went to a dressmaking school, but after she completed the course, she was never able to hold a sewing job more than three or four weeks because of her nervousness. She seemed unable to readjust herself and before long returned to the laundry, where she did work which far exceeded her physical strength.

Many of the juvenile cardiacs who came to the bureau were also neurotic. Some of the children who have gone to special cardiac classes have a tendency to become over-conscious of their disability. They give their illness as an excuse for being late or for malingering on their job. Anthony Brown was typical of this tendency. He attended a trade school where he took up jewelry. His work was good but he came and went as he pleased and refused to follow the general rules of the school. It was decided to try him out at work; he was so self-centered and temperamental, it was thought the discipline of actual work conditions would be good for him. Many positions were found but repeatedly he gave them up. Brown's cardiac condition is not a serious one, but his temperament is a definite handicap in his success at work.

Some of these stories give a rather gloomy picture of the potentialities of the cardiac as a steady, valuable employee. In spite of this, experience shows definitely that many cardiacs can prove very worth while workers and that most of these cardiacs who do work steadily are in better physical condition than when they are unemployed. By following up the reports of some of these cardiacs at work, one can see, in their classifications, changes which show a marked

improvement in their condition.

James Meehan, age 35, had been out of work two years when he applied at the Rehabilitation Bureau. He was a IIB cardiac and his own trade, that of an iron worker, was unsuitable and dangerous. He took two months training in a vulcanizing school. His physical condition was carefully watched and after one year of steady employment at this trade he has been reclassified as a IIA case. He can do heavier work than he was able to undertake at the time he started the training. He is now acting as assistant instructor at the school where he trained.

Frank Gregory, age 33, is another cardiac who has successfully been able

TABLE II.—OCCUPATIONS FOR CARDIACS.

For Women and Girls: Industry—Skilled	Process	Remarks
Millinery	Millinery processes...	Beginners must be cautioned against errands.
Lamp shades	Pasting or sewing...	
Dressmaking	Hand sewing and operating...	
Clothing manufacture	Finishing	Operating is usually too strenuous for IIA and IIB cases. The excessive speed of this industry makes it rather inadvisable. Small shops where there is hand sewing and embroidery prove good places often for cardiacs.
Underwear, blouses...	Hand sewing	
Clothing	Invisible mending...	
Laces and fine embroidery	Mending	
Dresses	Crochet beading...	Home work at this trade is sometimes suitable for IIB case.
Art work	Fashion design, etc.	
Clerical	Bookkeeping, stenography and typing...	
Celluloid	Painting, engraving...	
Institution	Sametress and information clerk...	
Wholesale house...	Sample mounting...	
Unskilled and Semi-Skilled:		
Buttons	Carding, sorting and packing...	
Candy	Packing, wrapping...	
Dolls	Packing, dressing...	
Hair net	Packing, examining...	
Hosiery	Packing, examining...	
Gloves	Packing, examining...	
Jewelry	Carding, boxing...	
Knit goods	Ribboning, examining...	
Lantern slides	Coloring	
Dress patterns	Folding, wrapping, etc.	
Pencils	Boxing, assembly...	
Piano action	Assembly, etc.	
Ribbons	Cutting, blocking, finishing...	
Drug supplies	Filling, labelling, finishing, etc.	
Domestic	Matron in clubs, etc.	

to change his trade. He was a baker by trade but the heat of the workshop seemed to aggravate his condition. After four months unemployment he came to the Rehabilitation Bureau quite disheartened. The course chosen was one in a barber school. The work has proved very suitable, and the doctor feels satisfied with his physical condition. Mr. Gregory is an easy talker and what is known in barbers' parlance as a "check getter." He is now employed as the manager of a barber shop.

Anna Black is another example of improved health and spirits after training. Anna is sixteen years old and her cardiac condition was not serious. She attended a public high school but had to stop her course be-

cause of the stair climbing. The girl had a very nervous temperament and this was aggravated by the constant friction in her home. Her father was very strict and allowed her few privileges. The girl brooded about the restrictions of her home. The rehabilitation counselor pointed out to the parents the harm they were doing her by not allowing her to lead a happier and more normal life. The father has since become less strict and the girl's entire outlook on life is altered. The girl has been taking a course in a commercial school and is progressing very well with this work.

Moore, a young man 20 years old, had been unemployed eighteen months because of his cardiac condition. The

only work he had done previously to his coming to the bureau was that of doorman. He was trained as a sewing machine operator on white uniforms. His condition has been carefully watched while in training and it has improved. He has been employed for some time at this work and it appears to be a successful choice of vocation.

Watch-repair work and jewelry have proven very successful courses for some of these trainees. Cardiacs seem more adapted for light

seated work of this kind than for any other. The Bureau has never tried training an adult for watch repairing but it would appear very suitable for a man to carry on in his own home if he were too disabled to work the whole day. Of the eight boys who have taken the jewelry course, most of them are now successful at the trade.

Some of the training courses given by the Bureau of Rehabilitation are listed in Table III.

In training cardiacs for work, the Bureau of Rehabilitation has found that a variety of schools must be used. There are disadvantages in placing a great many adult cardiacs in one training center. Because of their neurasthenic tendencies, segregation—(Continued on Page 760)

Editorials

WE HAVE discussed in earlier issues of THE NATION'S HEALTH certain of the administrative problems of the health officer, and his relations to the city authorities who furnish the sinews of war for his campaign. Scarcely less essential to success is the maintenance of a proper relation with the local medical profession.

Health Officer and Physician

The ancient barrier between public health and the private practitioner of medicine is being broken down with the progress of every passing year. On the one hand the physician in his individual practice is not only called upon to render more and more specific services to the state but in dealing with his patients he is every year devoting greater attention to the principles of health preservation as distinct from the alleviation of architecturally completed disease. As Sir Arthur Newsholme has said:¹

There will not be complete success until means are discovered for training and enlisting every medical practitioner as a medical officer of health in the circle of his private or public practice, and of securing his services not only in the early and prompt detection of disease, but also in the systematic supervision during health of the families under his care, and in advising them as to habits or methods of life which are inimical to health.

While on the one hand the private physician is thus becoming more and more truly a practitioner of prevention, the health department on the other hand is constantly facing a demand for the extension of its preventive service along lines which involve the organization of clinics of various sorts for the detection and preventive treatment of incipient disease. The trend toward expansion along such lines is clear and unmistakable; but if such developments are not wisely guided they are not only likely to provoke an active antagonism on the part of the medical profession but may work real harm to the progress of the general cause. It seems clear that wise progress in the future can be made only through wholehearted co-operation between the official health authorities and the local medical profession. The successful health officer must therefore be a man who can deal with these complex problems in the spirit of a statesman and who can preserve

1. Sir Arthur Newsholme. Public Health and Insurance. Baltimore, 1920.

intimate personal contacts with his medical colleagues, meeting them halfway in a joint effort to lighten the burden of preventable diseases. It will not be enough if he is merely the docile mouthpiece for temporary and ill-considered prejudices which may dominate a local medical group at a given moment. It will be equally disastrous if he goes his own way without reference to medical opinion and achieves a short-lived triumph by trampling on such opinion with the iron heel of official power. The health officer of the future must be a recognized leader among the medical men of his community and such leadership can only come through a combination of expert knowledge and character, of wisdom and personality.

THERE is a certain resistless logic about the public health movement which works itself out along surprisingly parallel lines in many different sectors of human life. At this season of the year announcements made by Lehigh, Antioch College, and many other institutions of learning remind us of the way in which such general tendencies are manifesting themselves in the development of machinery for the protection of the health college students.

University Health Services

First of all comes the control of the general environmental conditions which affect student health, the inspection of dormitories, the ventilation of classrooms, the provision of safe drinking water, the supervision of the swimming pool, the wrestling mats and the like. Something of this kind is of course provided for in every institution of higher learning. Soon it becomes evident, however, that a clean environment is not enough, that the human body itself manifests many defects which can, and must be, remedied if health and efficiency are to be secured. So a system of physical examination is introduced, first, perhaps, only for freshmen, then annually for all undergraduates, then for graduate students as well. Such a system soon demonstrates its inestimable value; and it is almost inevitable that the detection of physical defects should involve a certain amount of medical treatment as well as hygienic advice; for medical treatment is today often largely hygienic advice. Soon the treatment of ambulant disease is provided at the university dispensary; and in a few years the demand is almost certain to arise for the care of bed cases on what amounts to an insurance plan,

a fixed sum being added to the student fee to cover a complete system of health protection.

The course of development is in many respects strikingly parallel to what has happened in the public schools. So far as colleges and universities are concerned the path and the goal are so clear and inevitable that educational authorities who are still hesitating on the road might as well make up their minds to follow it through. As the advertising man and the salesman say: "Eventually, why not now?"

HISTORICALLY, the primary function of the industrial physician was to render first-aid in cases of industrial accidents. Then the scope of his work expanded to include the first treatment of cases of illness arising in the factory. Then came the physical examination of new employees, and, in certain plants, continued treatment of sickness and

Ambitious Industrial Service

home visitation of the sick in their homes by the industrial nurse. Exactly the same tendency toward an almost inevitable expansion is displayed in the field of industrial medical science. The development of the conception of industrial medicine to its full logical extreme has been worked out at the plants of the Endicott-Johnson Company at Binghamton, N. Y.

In this establishment the medical department renders without charge complete medical service, in plant, home, and hospital (exclusive of certain specialties), not only to all its employees but to all the members of their families. Three plant dispensaries and a maternity hospital are maintained with a staff of twenty-seven physicians and fifty-one nurses, while hospital service and certain types of special service are arranged for by the use of local hospitals and physicians. The total cost of the service is close to four hundred thousand dollars a year which, for sixteen thousand employees, amounts to about twenty-five dollars per capita but, for the actual population served (on the assumption of five to a family), to five dollars per capita.

This ambitious experiment in industrial medicine will be studied with keen interest by all thoughtful students of medical organization; and we hope to secure an extended description of its workings for a forthcoming issue of *THE NATION'S HEALTH*. Assuming the actual quality of medical service rendered to be at least as high as that which the industrial worker could obtain outside, the advantages of such a plan would appear to be enormous from a health standpoint; since

it is very clear that the men and women for whom such service is provided gratis will be far more ready to use medical aid as a preventive than if a direct financial responsibility were involved.

Whether the financial burden of what is practically a gratuitous insurance plan for medical service should be wholly borne by the employer, as in this instance, or should be shared by the employee, or perhaps by the state as well, involves problems for the economist and the sociologist rather than for the sanitarian. It may be pointed out, however, that the cost of the whole service is estimated at about 1.5 per cent of the payroll of the company; and apparently the firm feels that the outlay is warranted by the higher efficiency and the greater good will on the part of the employees which result in this provision for their health and that of their families.

A REPORT by Pearl and Reed¹ on the probable future population of New York City opens up alarming vistas for those who deplore the present tendency toward urbanization. Pearl's

New York's Future Population

formula corresponds to a curve which rises gradually at first, then rapidly and then more slowly again, a formula which is almost certainly more accurate than one which

assumes a straight line continuous increase. The metropolitan district of New York appears to be now only at the beginning of its period of rapid growth, a period which began about 1900 and according to Pearl should extend nearly to the year 2000 without appreciable slackening. If these estimates are correct the total population of the metropolitan district in the year 2000 will be over twenty-eight millions with a density of over five thousand persons per square mile. Within a small inner zone, including the present New York City with Hudson County and Newark, N. J., a population of nearly eighteen millions with a density of over forty-eight thousand persons per square mile is indicated. As Pearl points out, however, the population growth of a given densely populated area is dependent upon what goes on in less thickly settled regions from which its subsistence must be drawn. Much may occur within the next seventy-five years to save us from the problems created by a city of thirty million souls.

THE sewage disposal problem which confronts the second city of the United States is of more than local interest, on account of its inherent importance and also on account of the problems of general policy which are involved.

Chicago's Sewage Problem

The Sanitary District of Chicago was organized to devise and to execute the best methods

of eliminating the menace to health involved in the discharge of the sewage of the metropolitan district into Lake Michigan. Its primary purpose was accomplished by the construction of the great drainage canal which reversed the flow of the Chicago River and created a new channel two hundred feet wide discharging southwestward from Lake Michigan into the Des Plaines River and carrying the sewage of the city entirely outside the watershed of the Lake. For a time this method of disposal was notably successful. The attempt of the state of Missouri to secure an injunction against the operation of the canal on the ground of a menace to the water supply of St. Louis was dismissed; and the possibilities of dilution as a method of sewage treatment were strikingly demonstrated.

Dilution processes depend, however, for their success upon a delicate balance between sewage discharge and diluting volume. As the population of the district and the quantity of its industrial wastes increased, oxygen in the canal and in the river below became exhausted and it was obvious that the artificial treatment of the sewage before discharge must be provided for. The elaborate studies which have been conducted in regard to this problem have been presented in a previous issue of *THE NATION'S HEALTH*¹ and the progress already made in the actual treatment of Chicago sewage is described elsewhere in the present number by the Sanitary Engineer of the Sanitary District.² Chicago has done her part in coping with a difficult situation; but in order that success may be attained it is absolutely essential that she should be permitted to use the full amount of diluting flow from the lake (10,000 cubic feet per second) for which the canal was designed. The complicated legal history of the attempt to limit the volume of water thus diverted from the Great Lakes drainage basin is fully discussed by Mr. Pearse. It is sufficient here to point out that the influence of the canal upon lake levels is insignificant; that the limitation of the diluting flow of the canal to much less

than 10,000 cubic feet per second will entail a cost of over one hundred million dollars, and that effective engineering works which would really regulate the lake levels would cost only two millions and a half. Whatever interstate and international jealousies may be involved the engineering facts are clear. It is to be hoped that Congress will accept a rational and constructive view of the situation and take the necessary steps to legalize a sensible solution of the problem involved.

WIDE publicity has been given in the daily press to an article by S. Dana Hubbard¹ on the statistics of alcoholism in New York City, from which Dr. Hubbard draws sweeping conclusions in regard to the alleged failure of the prohibition laws. He cites figures which indicate that admissions to hospitals for cases of alcoholism, and arrests for

Alleged Failure of Prohibition

drunkenness, have increased between 1918 and 1922, apparently considering (and certainly leading the unwary reader to consider) 1918 as a normal pre-prohibition year. Fortunately, however, Dr. Hubbard quotes one more table, of deaths reported to the Health Department, from alcoholism, wood alcoholism, and acute alcohol poisoning; and these figures, unlike the others, go back to 1910. In his discussion of this table the author again uses 1918 as a norm and points out that the number of deaths from the three causes cited in 1922 (295 deaths) "is actually greater than that of 1918 (257) prior to national prohibition."

Perhaps Dr. Hubbard may not have heard that there was a war on in 1918, that a large proportion of the young men of New York were in the army, and that the rest of the population were in a somewhat serious and ascetic mood at that time. In any case, his table shows that between 1910 and 1917 the number of deaths from alcoholism and wood alcoholism and acute wood alcohol poisoning never fell below 565 and averaged 626. In 1918 it fell to 257. It fell further to 127 in 1920 and has since risen, but the figure for even 1922 (295) is only 47 per cent of the average for 1910-1917. There can be no doubt that the same relation would have been indicated for hospital admissions had the figures been fully quoted. The experience of 1922 is indeed disheartening but it does not show that prohibition does not prohibit but that it effects only a 47 per

cent reduction in the death rate from the causes concerned. That a man of scientific training should use the 1918 figures as a basis for comparison and ignore all the experience of previous years is a somewhat surprising instance of statistical fallacy. It deserves this editorial comment only because it is typical of much popular anti-prohibition literature, from sources of less seeming weight and authority.

THE generally higher incidence of bubonic plague in warm climates has long been obvious but it has remained for Robertson¹ to collect statistical data indicating the force and generality

Plague, Fleas, and Temperature

of the temperature factor in governing the spread of this disease and to suggest a plausible explanation. Robertson's figures indicate that plague of the bubonic type is roughly limited to a zone girdling the globe between the thirty-fifth parallels of north and south latitude. Of a series of nine million plague cases reported during a quarter of a century, 99.8 per cent have been from areas with mean midwinter temperatures of 56 degrees F. and over. If we exclude India, out of two hundred thousand odd cases 94.7 per cent have occurred in areas with a mean midwinter temperature of over 56 degrees, 4.5 per cent in areas with a mean midwinter temperature of 46 to 55 degrees and only 0.1 per cent in cities with a mean midwinter temperature below 35 degrees.

The explanation of these phenomena suggested by the author is the possibility that the rat flea is highly sensitive to low temperature and that in cold climates the fleas diminish in winter to such small numbers as to be unable to keep up the transfer of plague virus from one rat to another, so that the plague virus itself will shortly perish in its turn. The first step in the testing of this theory must of course be the determination of the actual prevalence of rat fleas at different seasons of the year and this study we understand is now being actively prosecuted by agents of the United States Public Health Service. If Robertson's views should be substantiated, his hypothesis will help to clear up many obscure points in the etiology of this still mysterious disease.

Department of Commerce reports indicate that more than fifteen million persons, or more than twenty-seven per cent of the population of the United States, live in zoned cities.

Habits of Posture As Related to Health and Efficiency

Symmetrical Bodies, With Hard Abdominal Muscles, and Organs Competent to Perform Their Functions

BY FLORENCE A. SHERMAN, M.D., ASSISTANT STATE MEDICAL INSPECTOR OF SCHOOLS, ALBANY, N. Y.

THE demand of the world today is physical and mental efficiency on the part of men and women in every position in life.

Human efficiency depends upon the strength and endurance which make it possible for a person to do continuous work satisfactorily. Hence, the importance of a well balanced healthy body in order to obtain maximum results. We are so accustomed to badly poised bodies and to seeing people both old and young who walk with shambling gait, that we scarcely notice these defects. We even tolerated a few summers ago the "debutante slouch" which is now yielding its harvest of badly shaped bodies and ill health. The posture of children in school and men and women at work is almost universally bad—bad seating is often responsible for this. Nearly every organ in the body is obliged to readjust itself to meet the conditions forced upon it by bad postural habits. In this paper, time will not permit going into all the results of the common faulty habits of posture. Take the slouch, the stooped shoulder for instance; this last favors inception of tuberculosis, and in girls and women tilting of the fundus of the uterus is found almost invariably—lying frequently beyond the median line of the body,—crowded over by the intestines which fall into the larger space on the lower side. Enteroptosis also is common with its fearful brood of toxic substances which lower vitality and render the body susceptible to disease. Normal poise of body in standing, walking, and sitting is an important element of health and efficiency because it places all the muscles and organs of the body in the best possible position for the performance of their functions.

Good Posture

What is good posture? (Ward Crampton)

"Good posture is that position of the body which makes it possible for a man to do his work, day in and day out, with no useless expenditure of

energy, permitting normal function of all organs of the body." Good posture is for life, and life is a test of endurance. Good posture indicates vitality, we know it when we see it—because we feel the strength behind it. There are four essentials to good posture: Head and chest high, back straight, abdomen flat.

We are all familiar with the various forms of ptosis: (1) *Skeletal ptosis*, the downward displacement of the bones shown in the drooping head exaggerates spinal curve, flattens the chest, etc. (2) *Visceral ptosis*, the downward displacement of the viscera; usually accompanies the skeletal. (3) *Circulatory ptosis* shown by venous stasis, a collection of the blood in the abdominal veins and arteries. (4) *Emotional ptosis*, present when there is depression of spirits, this showing the close correlation between the mental and the physical.

It is impossible to imagine anyone being riotously happy in poor posture. Men, women and children today are strong or weak as their abdominal walls are strong or weak. The importance of beginning early in child life to develop back and abdominal and foot gymnastics cannot be over estimated. Strong muscular walls hold the bulk of the digestive organs up out of the pelvis and help prevent intestinal stagnation. A straight back is an old good posture ideal and an excellent one. In olden days children were strapped to a board for some time in order to make them straight. We all have seen the old straight back chairs and the long wooden benches in the schools which our grandfathers and grandmothers used—children had to use their back muscles, and many of the older generations put this present one to shame. To acquire good posture is a simple thing to do, and such a serious thing not to do. The process is mental as well as physical. It means much to children in their plastic years. It is a health habit to be acquired early in life and maintained.

Any factor which limits or prevents

a growing child from engaging in what we term "normal activities" must be considered a menace to its health and taken into serious consideration. A child may fall well within the accepted limits as to weight and height and yet be so handicapped by physical limitation that normal activities are seriously interfered with. That posture which so largely determines the manner in which we use our bodies has a very decided influence on our activities and so on the health of the young and old will not be gainsaid I am sure by anyone who has given this aspect of development careful thought. Golthwait of Boston says: "To stand erect and walk easily, to have all parts of the body so adjusted that easy balance and brace may result is to be desired for far more important reasons than the esthetic; such elements are necessary for perfect health."

Poor bodily mechanics often explains why a child is not enjoying the health and development it should and may even explain acute conditions which may be affecting it. Therefore careful examination of posture should be a part of every medical examination and correction of the postural fault should be insisted upon.

In childhood the correction of faulty posture is comparatively easy. The child is but the forerunner of the adult. Its conformation forecasts what manner of man will result when maturity is attained. Hence the importance of beginning early. Every child has a right to be well born, to receive a symmetrical body,—with organs competent to perform their function. He also has the right to begin adult life without physical and mental handicap. We all know the long physical struggle that lies before the boy and girl who inherits the tall slender form, the one with long spinal column, narrow shoulders and hips with a heavy head balanced on a slender neck. Only under the most favorable environment and skilled physical direction can such a type hope to acquire the body sym-

metry and endurance needed in life. I believe the schools should place more insistence on the bearing of pupils not only in the class rooms but at all times. I believe the basis of our physical training should be good body mechanics. This would be almost revolutionary at the present time. If our physical directors succeed in giving to growing boys and girls good postural and good breathing habits, they will be rendering the greatest possible service. This is not to say that general athletics are lacking in value, but the basic thing should be good body mechanics. One needs but to glance at the backs of children seated in almost any classroom to see stooped shoulders and flat chests in the making. An examination of the seats and desks shows one cause.

No argument is needed to prove that the person who stands erect and is well poised is better able to attain success than the one who slumps. Good posture habit is not only a health measure but has decidedly favorable influence upon personality. The result is far-reaching when it is considered that the common postural conditions in school children include: Tilted head, round shoulders, crooked backs, bow legs, uneven shoulders, foot deviations, knock knees, and cramped abdomens.

The nurse can aid in these conditions by:

- (1) Noting the postural defects in her various contacts.
- (2) Referring all cases showing such defects to the school health and physical directors.
- (3) Emphasizing in class room talks the importance of good posture.
- (4) Making frequent suggestions to the individual children affected and supporting this work by contacts with parents.
- (5) Noting the adjustments of seats and correcting unsatisfactory conditions.
- (6) Including in health talks the subject of foot hygiene, and the importance of proper stockings and shoes.

The state of Ohio, whose population of about six million persons makes it the fourth largest in the Union, is served by six thousand physicians in active practice, according to the *Ohio State Medical Journal*. The A. M. A. directory lists eight thousand, of which number there are about six hundred in state, municipal, and industrial positions. The average is given as about nine thousand sick calls a year per physician.

Etiology of Rickets

THE history of rickets is that it has been enriched by a wealth of new hypotheses but few new facts, is a statement from Albu and Neuberg with which Edwards A. Park of the department of pediatrics, Yale University School of Medicine, opens a discussion of the etiology of this disease in the *Physiological Reviews*, January, 1923. Professor Park continues by saying that this statement made in 1908 is no longer true, for in the past four years facts of the greatest value have been discovered. A critical discussion of these facts then follows. The bibliography, containing 141 titles, including several papers by the author, attests the comprehensiveness of this paper.

"Rickets is a disturbance in the metabolism of the growing organism of such nature that the salt equilibrium, in particular as regards the calcium and phosphorus, in the circulating fluids is disturbed, and lime salts no longer deposit in the bones. Lime salts may not deposit because the ionized calcium in the blood is low, or because the ionized phosphate is low, or because both are low. When, however, the calcium in the blood is low, the formation of new bone and the destruction of old calcified bone (umbau) is greatly accelerated, and the pathological process takes on a distinctive character. But no fundamental differences exist between the low calcium and the low phosphorus forms of the disease. Increasing knowledge concerning rickets has made it necessary to broaden the view in regard to the characteristic pathology and admit to the disease all disturbances in metabolism in which lime salts cease to be deposited in the bones and cartilage."

The first detectable sign of rickets is probably a diminution of the inorganic phosphorus or calcium of the blood. It is most prevalent in those nations whose wealth and industrial prosperity have brought about the most complete change to artificial conditions from the simple environment which nature intended. It occurs chiefly in North America and Europe and is found almost exclusively in the cities. "Savages may starve and may become the victims of pestilence, but they do not develop rickets." Rickets occurs rarely in the Arctic regions and rarely in the tropics. In general only those animals that man has completely domesticated or those which he keeps in close confinement are sub-

ject to attack by this disease.

The extent of the disease in some cities is shown by the fact that 96 per cent of the infants dying in Dresden between 1901 and 1908 showed evidence of rickets.

The cause of rickets is a deficiency in the regulatory influence of radiant energy or of the unknown factor in food associated with it, but in all probability distinct from fat-soluble vitamin A. It is further stated that " . . . confinement, infection, bad hygienic surroundings (considered apart from the absence of radiant energy), exercise a deleterious influence in rickets, further weakening an organism already suffering from a disabled metabolism.

"The general character of the relationship of infantile tetany to rickets has become apparent, but the exact nature of the metabolic disturbance necessary for the development of tetany remains obscure If tetany can be considered a disease, then it is the same deficiency disease as rickets; it is cured and prevented by exactly the same means and differs from rickets only in the fact that the salt equilibrium in the blood happens to assume a special form or forms." Tetany appears to be a symptom complex which occurs in rickets when the disturbance in salt equilibrium is of such a nature that hyper-excitability of the nervous system is produced.

Professor Park closes his excellent bibliographical review with the following statement: "Rickets is indeed a price paid by man for his abandonment of a life of out-of-doors and a natural diet for life in houses and a diet in denatured foodstuffs; it is a sign of the operation of the immutable law of nature that nothing out of accord with her shall flourish."

Oregon has passed an act (*Ch. 28, Laws 1923*) to provide for a department of research and guidance in public schools in school districts having a population of ten thousand inhabitants or more, defining its duties and functions, defining the term "educationally exceptional" children, and authorizing the board of directors of such districts to establish special classes and special schools for such children, and authorizing the board of directors to require the attendance of such children at such schools.

The Parent-Teacher Association in the United States now includes in its membership 537,000 persons.

Iodin Treatment of Water*

BY BEEKMAN C. LITTLE, SUPERINTENDENT OF WATER WORKS,
ROCHESTER, N. Y.

THE Water Bureau and Health Bureau of Rochester, N. Y., working together, have evolved a plan for the successful iodine treatment of public water supplies for the cure and prevention of goiter. It is stated here with especial emphasis on the value of preventive methods in health work in the hope that it will be earnestly considered by health departments and medical officers wherever goiter presents an extensive problem.

It is to be understood that the author is not stating on his own authority any of the medical aspects of the question, but has widely gleaned these matters from the writings and opinions of medical men in high repute.

Simple goiter, generally recognized as a swelling of the neck due to the enlargement of the thyroid gland, has probably come to the attention of everyone. The extent to which goiter prevails is seldom appreciated, however, for in the entire world there are but few countries free from goiter districts, and sporadic cases exist in every section and in every nationality in the world.

In North America, the disease is endemic, that is, especially marked and continuously prevalent in the whole of the Great Lakes region and in the basin of the St. Lawrence and in the North-west Pacific region.

The seriousness of the disease itself can be learned with but little investigation. There is a definite relation between disease of the thyroid and cretinism or idiocy, marked by physical deformity and degeneracy.

Statistics are not always reliable, but it is safe to say for instance, that in this region along the Great Lakes, in Detroit or in Rochester, that seven out of every one hundred school children are afflicted with goiter, and further, it is conservative to say, that a large proportion of all the women consulting physicians, have the disease.

Certainly this is a disturbing condition and any promising suggestion for its alleviation should receive at least respectful and thoughtful attention.

Now, iodine is a natural constituent of the normal thyroid gland, and one that is essential to normal thyroid

activity. The amount of iodine required is exceedingly small, but when this amount is absent, the thyroid gland seeks by increase in size and surface to make up for this lack in iodine, and goiter is the result. In fact goiter has been described as an adaptation to "iodine-deficient" nutrition. It follows therefore that the treatment for goiter, now pretty generally practiced, is giving of very small dosages of iodine.

An accredited prescription is: 1/10,000 of a gram of iodine administered daily over a period of fifteen to twenty days, this given twice a year, once in the spring and repeated again in the fall.

A recent study from the laboratory of the University of Minnesota, by Dr. J. F. McClendon, shows very clearly the inverse ratio between the amount of iodine in surface water and in the distribution of goiter. In the neighborhood of the sea, the air and water contain very much more iodine than in inland places, and these places distant from the sea, exhibit the goiters.

What we propose is really very simple, namely, to introduce into the drinking water a very minute quantity of iodine and thus bring to the human system and the thyroid gland, that which it needs, and otherwise lacks, to function properly.

This idea of dosing every one willy-nilly is startling but not unknown, and not altogether revolutionary. For instance, in Switzerland, where goiter is very prevalent, it was decided in one canton last February to incorporate a small amount of iodine in all the table salt used. All civilized persons take daily, a certain quantity of salt, and, as it is inexpensive, and as the Swiss Government can control this article of food, it seemed to be the proper carrier for the iodine. This way of doing it—even if it were possible in this country—does not seem to contain, however, the advantages of the water supply method.

In recommendation of our plan in Rochester, Dr. Goler, the health officer, makes among others, the following recommendations:

(1) We always have in Rochester, among our children, more than two thousand cases of preventable goiter.

(2) We have so much simple goiter

because of the absence of minute quantities of iodine in our food and drink.

(3) We may prevent this goiter by the addition of minute quantities of iodine to the drinking water 2/10,000 of a gram to a gallon, in the form of iodine of soda.

(4) Iodine seems to be required by the body and when taken into the body in these minute quantities, it is fixed by the thyroid gland and so prevents its enlargement, and consequent goiter.

(5) If we put iodine in the water, it will only be necessary to dose the water twice a year, for two weeks. This would require daily 13.3 pounds of iodine of soda for two weeks, or 372 pounds at \$1.80 per pound, or \$1,785 a year.

(6) Goiters of course are subject to cure only after they have developed. We should like to prevent them. To prevent these goiters would cost less than two thousand dollars a year. The addition of this minute quantity of iodine would also affect favorably young persons already having goiters. It would not affect that form of goiter known as "Grave's Disease" or exophthalmic goiter. It would not affect the older types.

The Water Bureau at Rochester has already started this treatment of the water. At one of our reservoirs, from which is drawn all of the water entering the city mains, we have dissolved daily—for a period of two weeks—sixteen pounds of iodine of soda, a slightly greater amount than first suggested.

Our consumption of water during this period was approximately twenty-five million gallons per day. In the laboratory of the Health Bureau and checked up by chemists in the University of Rochester laboratory a close track was kept, and it was found that the iodine content in the water increased from one part in a billion parts of water before the experiment, to twenty parts in a billion.

Next fall the dose will probably be increased, as it is planned to get about fifty parts of iodine to one billion parts of water.

Such a water, prevailing for two or three weeks twice a year will, it is calculated, give to those drinking of it freely, approximately the required dosage of iodine to bring to a close the story of simple goiter in Rochester. Perhaps from this point, its extinction even throughout the world will begin—Who knows?

Eye Strain of School Children

*When Absolute Freedom of Adjustment for Comfort Is Not Permitted,
Then Mechanical Measurement Must Make the Essential
Adaptation to Physiological Needs*

EYE STRAIN as found among school children dates from the very beginning of their entrance into the school building, although it is less acute in the kindergarten classes because of the arrangement in the seating of the children. "I first noticed this several years ago while making an inspection of kindergarten rooms," stated Dr. Isaac D. Brown, medical inspector of public schools, Seattle, Wash., in a recent interview. "It happened to be a very bright day and, while watching the children, it was noticed that several of them would move their chairs so that the light fell upon their sides or backs, while those who sat facing the light were scowling. Upon examination of the latter it was found that the pupils of the eyes of these children were contracted. Upon inquiring of the children who moved their chairs why they did so, they could give no explanation, but I kept this incident in mind and frequently observed it. The teachers, when asked regarding the light, invariably said that they had very little, if any, trouble because the seats were not fixed and the children were permitted to move their chairs about so as to obtain the best light possible."

"When the child leaves the kindergarten for rooms fitted with the stationary seat, his exposure to eye strain becomes a factor in every school room where the seats are placed parallel to the light. It is not only the arrangement of the seats, but their finish as well that is of the utmost importance. The highly polished surface of the ordinary seat is as great a single factor in causing eye strain as anything we have to contend with. The architect, in times past, was perhaps one of the greatest single causes of eye strain. He would never meet one half way in discussing

the lighting of the building. He had certain lines which he felt must be followed. In others words, beauty must be maintained regardless of the effect it may have upon those who were compelled to occupy the buildings, but of late there is a tendency to follow specifications of experts and sacrifice beauty lines for the benefit

(3) The glare from the highly polished surfaces.

(4) Story or study reading at home by poor lights or none at all.

(5) Distance at which work is held.

(6) Poorly lighted black boards.

Most of the causes of eye strain are preventable. At least, all of the

factors entering into the causation during school life may be eliminated by a re-arrangement of the seat so as to bring the light over the shoulder rather than across and in front of the eyes. There is at least one desk on the market that practically solves this problem and that is a desk which is constructed so that when the child is seated the source of light falls over the shoulder, doing away with all glare and preventing contracted pupils from strong light in the eyes.

It has been pointed out that something should be done to improve the condition of pupils seated at the ordinary rectangular desk with the strong light at the left and front and also with strong rays of light reflected from the highly polished desk tops to the left and front of the pupils.

As it is difficult to change or modify the lighting of a classroom the logical solution seemed to be to plan equipment so that the child will be turned from the source of light as much as possible, while at the same

time his position will remain uniform with regard to the other desks and aisles.

For a number of years architects have arranged the seating of class rooms so that the aisle and desks extend diagonally with the room, but this has been found a rather unsatisfactory arrangement in respect to appearance as well as the maintenance of discipline. A desk designed to combine the advantages of both systems is rhomboidal in shape, thereby turn-

The desk pictured is so constructed that the light falls over the shoulder of the child when seated, and all glare is eliminated.

of the children."

"Eye strain is variously estimated as affecting from 3 to 6 per cent of all school children. All of this is not due to poor lighting of schools, but I feel that most of it may be so charged. After years of observation, I would attribute eye strain among school children to the following causes:

(1) Poor lighting in the school room.

(2) The arrangement of the seats.

A class room in the high school of Modesto, Calif., where seating and lighting arrangements under the principles outlined favor the eyes of the children.

ing the normal line of the pupils vision 22.5 degrees from the center line of the aisle, which remains paralleled with the side of the room. This gives protection from the two sources of glare, the windows and the reflected light from the desk tops.

The major axis of the desk being longer than the minor axis and lying in the direction of the forearm when writing, support of the arm is per-

mitted even when writing at the bottom of the paper. An added convenience is that sweeping the floor in rooms equipped with the type of desk described is easier and quicker because the supports are paralleled and staggered instead of parallel and opposite as in the rectangular desk, a feature which has been greatly improved by the new pedestal support now a part of this desk.

Swimming Pool Sanitation

SWIMMING pool sanitation is a problem that cannot be put off; it is present now, and becomes more urgent with each new pool constructed. states the report of the Committee on Swimming Pool Sanitation to the League of Minnesota Municipalities. Forty indoor pools and ten outdoor pools were included in the report, and about 75 per cent of them are being operated without information as to their sanitary condition.

The immediate problem in Minnesota is the adoption of standards for the maintenance of swimming pools. Quoting from the report:

At present there is no commonly accepted standard, as in the case of drinking water, so the committee as a basis for its work has taken the one proposed by the committee on bathing places appointed by the Conference of State Sanitary Engineers. Last winter a series of bacteriological examinations were made on nine swimming pools: seven equipped with ultra

violet ray sterilization apparatus, one with a chlorin machine, and one emptied and refilled every day. Later on at one of the pools having an ultra violet apparatus a chlorin machine was installed, permitting a comparison of the two systems under identically the same operating conditions.

A total of 125 samples was taken from the pools using the ultra violet rays for sterilization, one of which, by the most liberal interpretation, came within the proposed bacteriological standards. The ultra violet ray sterilization apparatus produces sterile or nearly sterile water when functioning properly; but the amount, 3,000 to 6,000 gallons per hour, added to the total volume of the pool, considering that pollution is simultaneously introduced by the bathers, is not large enough to keep the water in the pool within the proposed bacteriological limits. The quartz tubes enclosing the ultra violet ray lamps must be kept perfectly clean if the

apparatus is to function properly. In no one of the pools when first examined was this being done and as a result little or no benefits was obtained from the apparatus.

From the two pools treated with chlorin fifty samples were taken, 90 per cent of which were satisfactory judged by the proposed bacteriological standards. The action of chlorin is not limited to the water recirculated as with the ultra violet ray apparatus, but extends throughout the pool. The chlorin dose can be administered with utmost accuracy and ease and the amount of chlorin necessary to keep the pool in a sanitary condition readily determined. This is common knowledge among those familiar with the use of chlorin in the disinfection of water supplies.

One pool examined was operated on the fill and draw system, viz., emptied and refilled once a day with fresh water; the conditions here more nearly resemble those found at outdoor pools. Twenty-eight samples were taken from the pool, no one of which came within the proposed bacteriological standards. Two reasons for this were found: (1) the pool was not cleaned when emptied; (2) the bathing load was too large, conditions which obtain in nearly all outdoor swimming pools.

The problems of swimming pool sanitation are well understood, proper sanitation costs but little, and the recommendations of the committee in this regard received the full support of the League.

North Carolina has passed an act (*Ch. 661, Acts 1923*) to create in the department of printing and labor a division devoted to the deaf, to provide for the appointment of a competent deaf man to take charge of said division, to enumerate his duties and authority, and to provide for his compensation and for the expense of such department.

The simultaneous appearance of eczema in a number of persons who worked in a bust factory is reported by Charles in *Dermatologische Wochenschrift*. In the manufacturing process a paste was employed which was made by acting upon starch with lye in order to swell the granules, hydrochloric acid being used afterward to neutralize the lye. The paste was exactly neutral, hence the cause could not be either the acid or the alkali, but was caused by the use of 0.05 per cent of formalin which was introduced to keep the paste from spoiling.

Injury to Foot and Ankle

THE foot needs to be considered from only two standpoints: weight-bearing and locomotion. It is a comparatively small part of the anatomy, and yet carries the weight of the individual comfortably if mechanically and anatomically perfect. The longitudinal arch is placed in the foot for one purpose, and one only,—to give spring to the walk. The plantar fascia runs from the anterior and plantar surface of the os calcis forward in a fan shape and attaches along the heads of the metatarsals and is the bow-string which holds the bow of the arch in position. The scaphoid is the keystone of the longitudinal arch. The plantar fascia and the scaphoid maintain this arch in position. If one or both are disabled for any cause, the arch is weakened.

Dr. P. B. Magnuson, writing in *International Clinics*, brings out very distinctly the difference between flat-foot and weak or painful foot. A true, rigid flat-foot is seldom painful, for it has fallen far enough so that the foot has reached a support, namely, the ground. The height of the arch, he says, has nothing whatsoever to do with the integrity of a foot. A patient may have a very high arch and yet have a very painful foot. Another person may have a very low arch and experience no pain whatsoever in his foot. Pain is brought about by a weakening of the ligaments or an overload placed upon the ligaments. This overload may result from a sudden change in occupation from a sedentary life to an active life where weights are carried; a rapid increase in weight may

cause it; or it may result from the weakening of ligaments due to illness, toxemia, infection, or injury. He goes on to say:

The diagnosis of a painful foot should be, and is, a comparatively simple matter if it is remembered that the weight-bearing line of the body should fall from the anterior

Showing the so-called orthopedic heel which comes forward under the rear portion of the longitudinal arch and relieves the weakened musculature of the foot.

superior spine of the ilium, through the middle of the knee cap, and into the middle toe. If the weight-bearing line is thrown over toward the great toe or medially, then more strain is thrown on the bow-string of the arch than should fall there. The overstraining of the fascia that results causes much pain and very definite symptoms.

In examining the foot of a workman who claims to have been injured and complains of pain in the arch, probably the most valuable diagnostic sign is pain at the attachment of the ligaments which support the scaphoid bone. The individual does not associate tenderness here with an injury to the arch because he does not know that this bone is the keystone of the longitudinal arch. A foot which is overstrained forces this bone out from the central line of the body, thereby straining its supporting ligaments and causing them to become tender.

A weak and painful foot may result from any injury to the arch which puts a sudden strain on the plantar fascia and on the ligaments supporting the scaphoid and weakens them. If material injury is done, a permanently weak and painful foot may result and the maximum amount of pain may not appear from a number of days following the injury, especially if the individual is allowed to bear weight on this foot. Therefore, the fact that a man received an injury to the back of his foot and continued to work for some days without complaint of disabling pain does not argue against a valid injury.

After a period of complete relaxation of the ligaments involved it is necessary to give the foot support. This can best be done by placing a wedge on the inner margin of the

heel, making the inner height of the heel one-eighth or three-sixteenths of an inch greater than the outer edge. If necessary, an extension may be added in the way of a so-called orthopedic heel which comes forward underneath the arch. The shoe should be of such strength in the arch that a soft support may be put between the sole of the foot and the inside sole of the shoe as will hold this support without breaking down.

In these times such shoes are easy to procure. They have in them an arch of springy steel between the layers of leather which cannot be considered a rigid support in any way, and which allows a proper spring in the arch. Piano felt cut in the shape of a wedge and strapped to the foot gives a very satisfactory support and answers also as a constant source of massage when walking. It molds into the arch of the foot and gives enough support to weakened ligaments to relieve pain without taking away their entire work and causing atrophy through disuse. In all injuries to the feet it is the business of the attending surgeon to see to it that a patient is fitted with proper shoes.

Especially should the person recovering from an injury to foot or ankle, and persons with chronic predisposition to weak feet, be instructed in proper standing and walking positions. This is not as we have been taught in school and in the army, to stand with the heels together and the feet at a 45 degree angle, but the toes should point exactly in the direction in which the person is facing.

Position for weakened longitudinal arch. When resting in a sitting position, the legs should be crossed with the outside of each foot resting on the floor and the foot inverted.

A typical instance of flat-foot (left). Compare with position of the right foot, which is normal.

When one considers the mechanics it is easy to see why this is so. If one walks north and his toes and his feet are at an angle of 45 degrees, one foot pointing northeast and the other northwest, his heel comes to the ground on its outer posterior surface, and as he steps the weight of the propelling movement falls on the

integral muscles of the foot are beneficial. These exercises consist principally of standing with the toes together and the heels separated and of rising on the toes, gradually increasing the number of times the exercise is employed each day. Flexion of the toes is beneficial and inversion of the feet while sitting. This can best

Showing incorrect (on left) and correct (on right) positions of the feet in walking.

ball of the great toe, which is inside of the foot and the place where the arch is subject to the greatest strain, a strain which is increased every time he steps and pushes forward with his foot. With the toes pointed exactly in the direction of travel, the heels strike the ground exactly in the middle and when the foot which is giving the propelling motion goes back, the weight of the body falls forward and is distributed equally over the ball of the foot and the five toes, throwing the major portion of the weight on the outer side of the foot, where it should be. Over-correction of this mechanical fault is made when the patient is at first trained to walk pigeon-toed.

Building up the inner margin of the shoe aids in acquiring this position and a shoe with a straight inner line, a bulging outer line, and with

be accomplished by attempting to pick up small objects from the floor with the toes as one would with the fingers. If these few mechanical principles are sedulously followed after foot injuries, much disability can be prevented for those who need to be on the feet constantly in the performance of their duties.

The integrity of the transverse arch is quite as important as the longitudinal arch to comfort and weight-bearing ability of the foot, and is quite as frequently prolapsed. Prolapse of this arch produces radiating pain down between the third and fourth toes which is extremely acute. If the arch has been down any considerable length of time there is also complaint of a feeling of walking on the bare bones of the ball of the foot and, if the condition persists, there develops callus at the point of great-

one-fourth to one inch thick, just behind the heads of the metatarsals. The pad can be made of felt or leather and should be built up to a thickness which is found to relieve the pain. Some cases, especially in women, can stand two full thicknesses of piano felt in this position.

In workmen with severe prolapse of the transverse arch, especially following injury, it may become necessary to put on what is called an anterior heel, which is a strip of leather the thickness of the sole of the shoe, which runs diagonally from the posterior margin of the head of the first metatarsal to the posterior margin of the head of the fifth metatarsal. This is nailed to the sole of the shoe. Injuries to the ball of the foot or heads of the metatarsal are so frequent and apparently conditions under which they may be relieved so poorly understood that this point should be kept in mind where there has been injury to the heads of the metatarsals. The same method may be employed to relieve strain on the metatarsal-phalangeal joints where there have been fractures into the joint. In the opinion of Dr. Magnuson, either a felt pad or thin leather insole placed on the inside of the shoe, or an anterior heel of leather nailed to the outside of the shoe is essential in all injuries to the heads of the metatarsals when the patient first begins to bear weight on the foot.

National Conference of Tuberculosis Secretaries Reorganize

The special committee representing the secretaries of local tuberculosis associations, the secretaries of state associations, and the National Tuberculosis Association has just issued its report on a scheme for proper co-operative relationships among the several groups. The plan contemplates the reorganization of the National Conference of Tuberculosis Secretaries, the recognition of the reconstituted conference as the official representative of state and local associations, and such alignment of committee work as will provide for co-operative solution of all problems encountered in tuberculosis work.

Showing correct way of walking—toes pointing exactly in the direction he is going. He strikes the ground with his heel exactly in the middle and as the weight is thrown forward it is distributed equally over the ball of the foot and all five toes.

the toe swung in will also aid materially. A further aid when resting in a sitting position is to assume a cross-legged posture with the outside of each foot resting on the floor.

Daily exercises aimed at strengthening the inverters of the foot and the

ext pressure. The presence of this callus is one of the best signs as to the length of time the arch has been prolapsed. This condition is easily relieved by placing a pad about one and one-half inches long and three-fourths of an inch wide, varying from

Dr. G. Sannerman, medical officer in charge of the Public Health Service of the port of Hamburg, is spending a month in the United States studying the methods of the United States health officers at the quarantine station, Staten Island.

Diseases Man Has to Fear From Dogs

NOW and again health situations arise which call for the inspection and isolation of household pets in families where infectious diseases may be contracted by them and widely disseminated in the neighborhood. Tuberculosis is such a disease, diphtheria is often thought of, and particularly the deadly rabies is directly attributed to the dog. Not much is written, however, on the measures necessary for protection from the dog. Even the physician is sometimes not in possession of data concerning some of the ordinary diseases which point to the dangers man runs from dogs. In the old days an almost essential aid as hunter, protector, friend, the dog now is kept merely as a pet, and as such is permitted to run unquestioned where he likes, to take what liberties he chooses with children, and to be far too familiar with master and mistress. Dogs as carriers of disease are discussed by Cameron in the *Lancet* (London) as follows:

The more important diseases which, in temperate climates, may be carried in this way to man are: Tuberculosis, rabies, skin diseases and parasites, and the various intestinal worms.

Tuberculosis is not infrequent in the dog, especially in large towns. Abundant opportunity for its contraction is offered in cows' milk and butchers' offal, but the disease is generally contracted from man. The dog's habits provide great chances of infection, and the danger to man in such a case is obvious. The remedy

suggests itself. The danger to human beings is too great to take any risk. Tuberculous persons should be permitted to have no pets. Whether suspected or not, the animals in any household should keep their distance and should never be allowed to clean up a plate after a meal.

Rabies occurs chiefly in the dog and is spread chiefly by dogs. The tendency of the affected animal to run long distances multiplies the danger. The disease manifests itself in the first instance by a marked change in disposition. At this stage the saliva is already infectious and the virus can penetrate any broken place in the skin or mucous membranes and communicate the disease to man. As a measure against this disease all dogs in England are subject to a six months' quarantine under conditions controlled by the department of agriculture. It is always preferable to confine a dog for observation rather than to destroy an animal suspected of rabies. The dog which started the epizootic in England is supposed to have been smuggled in by air.

The Skin and Parasites

The dog suffers from four kinds of ringworm and three forms of mange, two of the latter being transmissible to man. He is infested with two specimens of lice, neither of which will live on man, but one—*Trichodectes canis*—is very important as it acts as the intermediary host of dog tapeworm. The flea, though only a partial parasite, is represented by several species that will live on man. The first step of ridding house and dog of fleas is to destroy the dog's bedding.

The most important nematode oc-

curing in the dog is *Toxascaris limbata*, the eggs of which are easily ingested by humans, especially children, by unwarranted association with dogs. Another type of round worm frequently causes rabiform fits in puppies. About half a dozen forms of flukes (Trematodes) found in the dog occur also in man.

Of the tapeworms found in the dog two are of considerable importance. The double pored tapeworm found in the dog has been several times reported in man. This worm, which grows to about twelve or fourteen inches long, passes its cystic stage in the biting louse and in the two fleas—*Pulex irritans* and *Ctenocephalus canis*. The cystic stage is known as a cysticoid and a single insect may contain as many as fifty larvae. The gravid segments have the power of movement and they may leave the anus spontaneously and crawl into the hair, where they dry and disintegrate. The eggs thus released are taken up by the intermediate host and develop into the cysticoid stage. The infected insect is swallowed by the vertebrate host, either dog or man and the tapeworm develops in a very short time. It is full grown in a little over a month.

It is easy to see how infection takes place in children but from the number of cases reported in adults it is obvious that there has been undue intimacy with the dog. The animal has to lick himself to keep clean and the flea may easily stick to the tongue and so be transferred to china, lips, or anything else touched by the dog. Hall, giving statistics on this worm, notes that it has occurred seventy-six times in man and that as many as 238 individuals have

UNDERWOOD & UNDERWOOD

UNDERWOOD & UNDERWOOD

A motor dispensary sent out by the Peoples Dispensary for Sick Animals, New York City, is as much a health measure for people as it is for pets, for the household pet not only acquires human diseases, but transmits them widely. Safety as well as humanitarian considerations prompt their care.

California, too, has a health problem in dealing with rabies that is concerned with the care of pets. Prevention being more certain than cure, the Fresno city and county authorities are co-operating with a public effort to prevent an invasion of the dreaded and deadly rabies.

been found in a single host.

Most dangerous of animal parasites of the dog is *Echinococcus granulosus*—the cause of hydatid cysts in man and the domestic animals. Cystic stages, are often seen in animals killed for food. The tapeworm is seldom noted because of its minute size. The larvae makes its way through the intestinal wall in the blood stream and is carried to some suitable organ, frequently the liver, where it develops into the well known bladder worm. The presence of the hydatid is always accompanied by danger to the host, as the cyst may reach the size of a child's head. The infection in man can come only from the dog—from badly washed vegetables, from the hands, from the dog's mouth, etc. The dog in turn can be

infected only through carelessness in the disposal of infected meat by uninformed persons. This danger is probably the greatest that is run by man from the dog as the symptoms in the infected animal are the most vague and often absent; and there is no Pasteur treatment available.

Five other species of taenia infect the dog, but none of them in any way dangerous to man.

There are many other parasites of the dog of much less importance to man, which are dangerous to other domestic animals—serious danger—from the dog. The remedy is to treat the dog as a dog and not as a human being. He must be kept free of parasites, and all ailing animals in the household where tuberculosis is suspected should be sent to be tested.

screens should be provided and under no conditions should the hearths be placed over wooden floorings. Bedding should never be aired or dried before an open fire or close to a stove. Where rapid drying is desired, circulation of air by a fan is the safest method.

Clothes dryers should be of metal throughout and steam pipes should be protected by wire screening. Flames in gas mangles should be guarded. Gas irons should not be permitted. Pilot lights should be installed in circuits to all electric irons and current should never be left on when irons are not in use. Non-combustible stands with at least 6-inch clearance should be provided for irons when not in use.

Although electricity is the safest form of lighting, it should be borne in mind that excessive voltage will break down insulation and fuses must be properly installed and maintained to prevent overloading. Kinks in wiring will also break down the insulation. Gas-filled lamps become hot enough to ignite woodwork, paper or other combustible material with which they may come in contact. Wherever such danger exists, wire lamp guards should be used. Lamps hung on drop cords should not be tied or twisted or allowed to come in contact with gas pipes, nails or other metal.

Safety matches should be used in preference to the "striking anywhere" type and metal friction lighters should be used wherever possible for lighting gas lights and ranges. Irresponsible inmates should not be allowed to have matches in their possession. Smoking in bed should be absolutely prohibited.

Rubbish, waste paper, and soiled dressings are frequently burned in open fires in the yards. Because of the danger from flying sparks such material should be burned under boilers or in properly constructed incinerators.

In the dark, or smoke, or under panic conditions, passage through narrow corridors may prove difficult or impossible. Corridors should be wide enough to accommodate all who will use them at one time under any condition. They should be kept absolutely clear at all times, especial attention being given to the removal of wheel chairs, spare cots, and other obstructions which are apt to be left temporarily in the corridors.

All officials, physicians, nurses, attendants, and other employees should be carefully instructed regarding common fire hazards, the use of extinguishing equipment, and the method of sending in a fire alarm. In giving such instructions especial attention should be given to the instruction of new employees, who are frequently overlooked.

An editorial in the *Lancet* (May 12, 1923, 5202, p. 961) reports severe criticisms by Haldane, Collis and others of Robson's paper on miners' nystagmus, previously abstracted in the Digest for July.

Fire Prevention in Institutions

THE following recommendations regarding the prevention of fires in institutions made by the fire commissioner to the mayor of New York City are so important a basis for the saving of life and property that they are reprinted in full from the *Weekly Bulletin* of the Department of Health:

Many fires in institutions can be traced to defective chimneys, poorly installed stoves and furnaces, defective electrical equipment, careless handling of inflammable liquids, spontaneous combustion in accumulations of rubbish, smoking and carelessness with matches. It is, therefore, essential that the management of such institutions should realize the seriousness of the situation and contribute to the fire prevention measures by maintaining safe housekeeping conditions.

The most practical provision that can be made for egress in institutional buildings is an arrangement for moving occupants rapidly and in an orderly manner horizontally through fire walls or fire-resistive corridors, or across open bridges, to buildings or sections which are safe. Where buildings are large, they can be subdivided by standard fire walls equipped with automatic fire doors; thus dividing the building into two or more separate sections, with little danger of fire communicating from one section to the other before all occupants are safely out.

With adequate egress facilities come the education and organization of those responsible for fire safety, the provision of adequate alarms and systematic attention to fire and exit drills.

Great care should be taken in handling of gasoline for motor-driven ambulances, trucks or pleasure cars. Gasoline should be stored in buried and protected tanks and never handled in open containers. Gasoline should not be used for cleaning purposes, especially inside of buildings. Many of the metal polishes for brass work, ambulances and the metal work in buildings are largely com-

posed of gasoline and benzene and are highly inflammable. Naptha and benzene used as solvents for rubber cement applied to the mending of rubber gloves, hot water bottles, etc., are dangerous and should be excluded from buildings occupied by inmates. The same restriction applies to oils, paints and varnishes, which should be stored in isolated buildings. Linseed oil should not be used for oiling and polishing floors, but mineral oil compositions, which are safer, substituted.

Cotton, wool, gauze, flannelette, and bedding should be stored away from spark dangers.

Some institutions have motion pictures for the inmates at frequent intervals. The ordinary type of film ignites very easily, burns rapidly, and gives off a stifling smoke. Only approved machines properly installed in fire-resistive booths and attended by licensed operatives should be allowed. Articles made of pyroxalin plastic, commonly called celluloid, such as toilet articles, picture frames, toys, match trays, lamp shades, and candlesticks, should not be permitted inside these institutions.

Metal cans should be provided for rubbish and soiled cotton waste. All rooms in constant use should be swept daily and any accumulation of combustible material in basement and attics should be removed at once. Especial attention should be given to the removal of papers and other packing material from grocery store and supply rooms. All lockers and closets should be frequently inspected to prevent accumulations of old clothing and other combustible material.

Wherever steam pipes are found in contact with or close to woodwork of floors and walls, they should be removed or the woodwork protected. The danger lies in the heat of the steam pipes converting the wood into charcoal, which takes fire spontaneously.

Alcohol and kerosene heaters should be kept clean, filled outside the buildings and used only when necessary. Electricity or steam is much safer. Where fireplaces are used, they should be carefully safeguarded; close-fitting

School Baths Development*

*School Baths Are Justifiable Because of the Alertness After the Bath.
Personal Hygiene Because of This Service Extends to Better Care
for the Clothing and General Appearance*

SEVEN years is not such a long time, but when one looks back and realizes what has been accomplished during that period in the development of bathing in the public schools of Baltimore, it seems almost as if an eternity had elapsed, states Robert F. G. Kelly, superintendent, Baltimore Public Baths, Baltimore, Md.

A survey of the twenty-eighth annual report of the Free Public Bath Commission, for the year 1922, shows that a total of 218,376 baths were taken in the public schools of that city during the year. Looking backward to the twenty-second annual report, for the year 1916, we find that for about nine months, the attendance at the first school baths, at school No. 6, on South Ann St., was 30,400.

For a number of years, in its annual reports and by public agitation, the Free Public Bath Commission of Baltimore had endeavored to have a system of shower baths installed in the public schools of their city. As early as the year 1900, with the opening of its first indoor shower bath-house, facilities were provided and efforts were made to encourage bathing among school children. In 1902 a letter was addressed to the school board, offering to give free baths to any children sent by their teachers at any time. This offer was accepted and many children were sent. In its report for 1903, the Commission suggested to the School Board the advisability of establishing in certain crowded sections of the city, baths in the public schools, but through the lack of finances this could not be done then. In 1904, at the request of the school board, the Commission prepared and submitted plans for school shower baths, but nothing was done by the above board to put them

into effect at that time. In its report for that year, the Commission stated that "one of the gravest problems in school sanitation in the larger cities and especially in schools situated in the poorer sections, has been, not only to keep the schoolrooms in a clean and sanitary condition, but also to secure cleanliness in the dress and person of the children coming from houses which are but poorly provided with facilities for bathing." Year

help the children. From the beginning the baths were a success and at the close of the school year they were opened for the use of the general public. During the summer months the attendance was large and the baths proved a boon to this neighborhood, where there were no shower bath facilities.

In a recent conversation with the principal of this school, she stated that the baths had been a wonderful factor for good to the children and the neighborhood. The children go back to their rooms refreshed and alert for work and no ill effects have resulted.

In the latter part of 1916, after the success of the baths in School No. 6 had been demonstrated, a request from the principal of School No. 76, in Locust Point, was received, asking if bathing facilities could be provided for their pupils. This school, an old one, but with a corps of efficient workers, who, under many handicaps, had been working along modern lines, was located in a section which had few bath tubs and the children came from

Baths in School No. 17, Eastern and Linwood Avenues, Baltimore, Md.

after year, in its annual reports, the Commission stressed the need of these baths, but were unable to persuade the School Board to install them, until about the year 1913, when ten showers were installed in Public School No. 6, on South Ann St., a neighborhood consisting of people largely of foreign birth.

It was not until the year 1916, however, that these baths were put into use, after the Bath Commission had agreed to pay all expenses in connection with their operation. With the cooperation of the principal and her efficient corps of workers, a schedule was made by which each pupil was allowed twenty minutes a week for a bath.

Care was taken that the attendants, one man and one woman, should be of the type that would encourage and

homes where they had not been able to receive much personal care. Two portable baths, with seven showers in each, were erected on a lot in the rear of the school and a schedule was arranged by which each pupil could bathe at least once each week. The results were very satisfactory and in an enrollment of over nine hundred, practically all made use of the baths. In the latter part of 1921, a large, modern school building was erected in the neighborhood and shower bath facilities placed in it. For the year 1922, the first full year of their operation, a total of 62,115 patrons was recorded. The development was especially marked by the use of the baths by the general public on Saturdays, on nights during the season when the gymnasium was

*Condensed from an address by Robert F. G. Kelly, superintendent, Baltimore Public Baths, before the twelfth annual meeting of the American Association for the Promotion of Hygiene and Public Baths, Jersey City, N. J., May 11-12, 1923.

in operation and during the summer months.

A Forward Movement

By the end of 1920, baths had been placed and operated in three schools and the success of the work was so marked, that in 1921 a communication was received from the Board of School Commissioners stating that the Committee of the Board of School Commissioners on Hygiene-Physical Education had made the following recommendations:

(1) That, in planning future school buildings and improvements to present buildings, advantage be taken of the experience and counsel of the Public Bath Commission and its superintendent in the matter of installing baths in public school buildings.

(2) That the most cordial cooperation be established and maintained between the School Board and the Bath Commission in the matter of having public school baths open after school hours and during vacations as public baths under the direction of the Bath Commission.

During the year 1922, at the request of the school board, the commission prepared a standard set of plans for shower baths to be used in the new schools to be constructed under a recent school loan. These plans, calling for ten showers each on the boys' and girls' sides, with an additional open shower room on the boys' side, to permit of mass bathing, were presented to ten firms of architects who are planning the new schools. Some of these schools are to be placed in congested sections where the need for bathing facilities is great and it is hoped that when these are completed, a large extension of bathing facilities to pupils and the general public will be possible.

The mayor, recognizing the valuable services of the Bath Commission instructed each member of the Board of Architects to get in touch with the Commission to discuss details for working out the problems of bathing facilities in the schools.

Baths for Colored Pupils

An interesting development during

the year 1922, was the opening of baths in two schools for colored pupils. Living in narrow alleys and in congested neighborhoods, where bath tubs are few and far between, the need for bathing facilities among the colored people is great. In a new school, erected in 1921, shower baths were placed and these were put into operation in February of 1922. From the beginning the facilities—four showers for boys and four for girls—were taxed to their limit and we feel that the total of 39,937 patrons in a little over ten months, speaks much for the appreciation of the baths by the children.

The other school was an old one in the southeastern section of the city. In June, at the request of one of

Of this, we are giving you two dollars for a needy family, two dollars for a little work here in the school, \$2.50 to the Empty Stocking Club, which is sending tickets to the needy little ones here for next Saturday's treat, the balance, sixty-six cents for comb and brush for the bath. A balance, ten dollars, we have in bank for the social and general needs of bath." And this was from children, who for the most part live in alleys.

School Baths Employees

From observation and information gathered from various sources, we feel that in cities where "School Baths" have not been a success, the fault usually can be attributed to the fact that the operation of the baths has been placed in the hands of janitors and janitresses, and to those who are familiar with the usual type, it would seem a marvel that they ever could be successful under such auspices. In our work we have had to exercise much care in the selection of the attendants and to the fact that we have been able to get men and women of high type, can be laid much of the success of the baths. In many cases, the woman attendant has to be a mother to the children, and in fact in certain sections, the children get far more from her in the way of personal attention, help and advice, than they are able to get in their own homes.

Aside from the beneficial effects derived from the mere matter of cleanliness, a very important feature of the work at the school baths, which has developed through the interest taken by the attendants, is a general inspection of the physical condition of the children patronizing the baths. The attendants have taken a deep interest in this phase of their work and have rendered a very valuable service to the community by personal inspection for minor abrasions or eruptions of the skin, or, where conditions are too serious for them to take the responsibility, by seeing to it that proper treatment is secured for the children at the hands of family physicians or at public dispensaries. The average number of cases reported and treated from each school has

Old class room converted into shower room at School No. 108, South Caroline Street, Baltimore, Md.

the members of the School Board, an inspection was made of the above school, to see if it would be possible to install a bathing equipment at a moderate cost. As a result of this inspection, five shower baths were placed in one of the classrooms. These baths were opened in July and were used by adults and children during the summer months. Beginning with the fall school term, practically the entire enrollment of the school, nearly four hundred, made use of the baths. To show the far reaching effect of baths in the schools, at the above school a small club, known as the "In-as-much Club" was formed. One of the qualifications for membership is that the applicant must be a regular user of the baths.

A letter from this club to the author says: "The Club is spending \$7.16 for a little Christmas offering.

been about twelve hundred a year.

In many instances, children have been taught the proper way to wear their clothing and to keep them in repair. Many cases of destitution have been relieved, which would not have been known had it not been for the baths. We feel that the remarks made by Dr. Baruch, president of the American Association for Promoting Hygiene and Public Baths, in his address at the Baltimore Convention in 1916, on "School Baths," cover our experience. We quote as follows: "Baths exercise a vital influence indicated not only by the appearance of the little ones, but by their alertness in study after the bath. The

children return to their classrooms more refreshed and alert for work than they would after a half hour's exercise in the gymnasium. We believe that the bathing habit formed in school, will continue through life. On the moral side, a child when clean has more respect for himself and is more responsive to law and order."

At the present time our Commission is operating baths in seven public schools and the pupils of another school use two portables opposite it. At all times has harmony existed between the School Board officials and those entrusted with the management and operation of the baths in the schools.

unemployment protection is based on President Loree's view that one of the most constant irritations in the minds of many employees is the feeling of resentment, whether well or ill founded, against the foreman immediately directing their work. The indemnity to the discharged worker amounts, from another point of view, to a penalty on the company when a foreman discharges a worker for insufficient reason. It was believed that by giving the employee this assurance of at least partial support in case he had to hunt a new job, not only would foremen be deterred from making capricious discharges, but the employee, realizing this penalty on caprice on the part of the foreman, would be disposed to minimize personal incidents between himself and his foreman which he might otherwise magnify into a personal injury or abuse.

Employees Group Insurance

AN UNUSUAL feature of protection to workmen is embodied in the unemployment insurance paid by the Delaware & Hudson Company, Utica, N. Y., to employees discharged with cause, at the rate of fifteen or twenty dollars a week, depending on the rate of wages, for a period of six weeks after discharge. This unemployment insurance, added to the several other types of group insurance covering sickness, accident, death, unemployment, and old age, is reported by *Greater Utica* as probably the broadest program fostered by any industry in the country.

Thirteen thousand employees are insured against some or all of the risks named.

May Carry Additional Policy

Ordinary death and total disability insurance is provided by the company, without charge to the employees, in the sum of \$250 for employees of over six months' and less than two years' service; and \$500 for those of more than two years' service. This free insurance is supplemented by extensions on a contributory basis. Any employee thus insured by the company may secure an additional \$250 or \$500 by paying the very low premium for this additional amount. On policies from \$1,000 up to a maximum of \$5,000 the company pays a portion of the premium, so that any employees co-operating with the company under this plan can have a total insurance of \$1,000 at a cost of 60 cents a month; \$2,000 for \$1.20 a month; \$3,000 for \$1.80 a month; \$4,000 for \$2.40 a month, or \$5,000 for \$3.00 a month. The total insurance allowable in any case is the mul-

tipile of \$200 nearest to the average annual wages of the employee for the two preceding years.

Loss by Sickness

Loss of wages by sickness is covered by a policy providing benefits of fifteen dollars a week for a period of twenty-six weeks, beginning with the eighth day of incapacity. The premium on this insurance, which is \$1.26 a month or \$15.12 a year, is paid wholly by the employee.

Loss of wages by accident, exclusive of injuries which are covered by workmen's compensation laws, is covered by a policy carrying payments of fifteen dollars a week for a period of twenty-six weeks, beginning with the eighth day of incapacity. Premiums for this insurance, amounting to 24 cents a month or \$2.88 a year, are paid wholly by the employee. This accident policy covers the employee against accidents during the entire twenty-four hours of each day and supplements the protection afforded by the compensation laws, which, in principle, cover only working hours.

Extra-hazard insurance covering death or dismemberment from any cause, including accidents covered by compensation laws, and carrying a double indemnity for death occurring in the course of duty, may be taken by employees under sixty years of age, at the rate of \$4.00 per \$1,000 of indemnity, this premium being paid wholly by the employee.

Unemployment Insurance

Unemployment insurance is open to employees who are carrying two of the three contributory forms (additional life, sickness or accident). This

Recapitulation

Figures for all forms of Delaware and Hudson insurance, from April 1, 1922, to the end of the year, are as follows:

Life insurance, including both free and contributory policies; number of claims handled, 94; total benefits paid, \$97,050; number of employees insured free was 8,176; the number carrying additional contributory insurance was 6,665.

On health insurance (premiums paid by employees) the figures are: final settlements made, 263; claims drawing benefits December 31 were 36; number insured, 4,328; total benefits paid, \$30,111.35.

Ordinary accident insurance shows: final settlements made, 43; claims drawing benefits December 31 were 8; number insured, 4,884; total benefits paid, \$3,786.99.

Accidental death and dismemberment insurance shows: claims handled 8; total benefits paid, \$13,100; number insured, 3,821.

Unemployment insurance shows: claims handled, 8; benefits paid on 5 claims, at \$90 each, and 3 claims at \$60 each; total paid, \$630.

Total benefits of \$144,678.34 were paid on a total of 460 claims under all heads.

The San Francisco budget allowances for the current year show increases of \$46,000, or 6 per cent for playgrounds; and \$42,988, or 12 per cent, for health. A net increase of \$412,000, or twenty-eight per cent, is allowed for school building, equipment and maintenance.

New Principles in Bacterial Immunity and Treatment of Infection

Dreyer's Defatted Antigens May Mark New Era In Immunology

EVERYONE interested in the public health will find the recent work of Professor Georges Dreyer of Oxford of great significance. If further studies bear out the implications of preliminary finding and reports, the hope for an efficient weapon against the great white plague may yet be realized.

Professor Dreyer, in his paper on "Some New Principles in Bacterial Immunity, Their Experimental Foundation, and Their Application to the Treatment of Refractory Infections," published in the *British Journal of Experimental Pathology*, June, 1923, states that after a survey of the field of vaccine therapy he was impressed with the fact that in general the successes of bacterial therapy and prophylaxis had been attained with non-acid-fast and Gram negative varieties, while failures have been frequent in the attempts to utilize in the same way varieties of acid-fast and Gram positive bacteria. Exceptions are of course noted but the general division is, in the words of the author, "striking."

Since acid-fastness has for a long time been known to be associated with the presence of certain waxy, fatty, or lipid substances contained in the Gram positive bacteria, it was reasonable on *a priori* grounds to associate these substance with the failure of attempts to secure immunization by bacteriological means. From this preliminary reasoning it was decided to attempt the extraction of these lipid substances with a view to utilizing the defatted bacteria in therapeutic procedure.

It soon became plain, after preliminary experiments along these lines, that something more than simple extraction with ordinary fat solvents was necessary if the hopes of success were to be realized.

The fact that tuberculous tissue fixed in formalin, tends to show (after sectioning and mounting) fewer organisms than portions of the same tissue fixed in perchlorid of mercury, furnished the first hint as to a method of approaching this problem. Thinking it possible that the formalin destroyed in some degree the condition of acid-fastness, thereby making

some of the organisms undemonstrable by staining, treatment along this line was instituted, but such treatment with strong formalin for various lengths of time did not produce the desired result. It was then thought that some of the many other agents utilized in the preparation of tissue sections might also be in part responsible for the small number of bacteria it was possible to demonstrate in such sections. Knowing that bacteria killed with formalin retain their antigenic properties, as they also do after simple extraction with acetone, a combination of these two was tried.

The result was a reduction of the Gram positive condition to a Gram negative one. The next step was to study the capacity of bacteria to produce immune substances in the body following such treatment, (which was easily demonstrated) and finally by animal experimentation to discover whether such antigens exert a definite curative effect.

To make the preparation and use of such antigens more clearly understood, the following brief description of the application of the method to the treatment of one particular disease is given. This description is of course much abbreviated; it gives only the main features and many of the technical points are omitted.

Tuberculosis Antigen

The major portion of Professor Dreyer's work has been done with *B. tuberculosis*. In preparing the tuberculosis antigen the bacteria are grown for two or three weeks on the surface of glycerin broth and then transferred to an agate mortar. A few drops of formalin (40 per cent formaldehyd) are added and the bacteria ground to a thick homogeneous paste. From time to time more formalin is added and the grinding continued until from 150 to 200 c.c. of formalin has been added for each 5 grams of the bacteria as weighed wet. This suspension is then maintained at a temperature of 100 degrees C. for four hours, following which it is filtered through calcium-free filter paper and the residue washed three or four times with acetone or until

100 c.c. of acetone has been used.

The residue is placed in the extraction thimble of a Soxhlet apparatus having ground glass joints. The apparatus is then placed in the water bath in such a way that the extractor is partially immersed and the top of the thimble is at approximately at the same level as the water in the bath. With the temperature of the water bath at 65-70 degrees C. extraction is allowed to continue for twenty to twenty-four hours.

At the end of this time the insoluble residue is dried and ground in a sterile mortar. If the condition of acid fastness has not been removed it may be necessary to repeat this process as many as four times when the bacteria are extremely resistant.

The next step is the actual preparation of the antigen from the defatted organisms. One-tenth of a gram of the extracted bacteria is ground with sterile saline (0.9 per cent) until a paste is obtained. This is gradually diluted up to 10 c.c. while the grinding is continued. The suspension is then centrifuged five to eight minutes at 3,000 R.P.M. The supernatant liquid is drained off and suitably diluted with saline containing 0.15 per cent formalin. The residue in the tube is then dried and weighed; the value obtained being then subtracted from the original 0.1 gm. The difference thus obtained is obviously the weight of dry defatted bacteria contained in the antigen suspension. This stock suspension is then diluted in such a manner that 1 c.c. contains one fifth of a milligram of defatted bacteria. This is the *B. tuberculosis* antigen.

Defatted tubercle bacilli can be digested by trypsin, and by animal experimentation the action of this antigen was shown to be specific.

Guinea pigs inoculated with a strain of human tuberculosis ordinarily fatal to them in six to eight months were given injections of the antigen when the progress of the disease had become marked. The treated animals regained their weight and to all external appearances their health. These animals were later killed and subjected to post mortem examinations; the examinations re-

vealing apparently healed tuberculous lesions.

Similar experiments were in process with rabbits at the time of writing the original paper. The indications were, at that time, that results similar to those of the guinea pig experiment would be obtained.

Experiments with *B. anthracis* grown at 42-43 degrees C. show that under these conditions the organisms tend to lose their power of retaining Gram's stain and that this change is also accompanied by a lowered resistance to the bactericidal action of normal horse serum and to immune serum from rabbits immunized with defatted anthrax antigen.

These findings are of interest in supplying an explanation for Pasteur's method of vaccination against anthrax by the use of cultures grown at temperatures above the optimum.

Professor Dreyer is continuing experiments with the production of defatted antigens from several other microorganisms.

Tuberculosis in Man

The point which overshadows all others is, naturally, the treatment of tuberculosis in man. If the tuberculosis antigen could be digested by trypsin, as had been previously shown, it was hoped that it would also be susceptible to the disintegrating action of the body fluids of man.

No local reaction was produced when the antigen was injected into healthy animals and it was thought safe to try it on man. In the first attempt minute doses were tried on two patients with acute febrile tuberculosis of the lungs and pleurae, who for a long time had been steadily growing worse. No untoward results followed but since the doses were so small it was not possible to draw any conclusions regarding beneficial action.

Encouraged to try treatment on a larger scale the aid of others was enlisted. In reporting on these results in his original paper, Professor Dreyer refrains from any lengthy report, partly to prevent any bias to the report and partly because the treatment had been in process for but a short time. The author quotes, however, from a report from Drs. Field and Webster, under whose care the treatment was being used, the statement of these doctors which in part as follows:

We have under treatment with Dreyer's antigen sixty cases of tuberculosis; . . . most of these cases have been under our personal observation for considerable periods up to five years, and have been se-

lected for treatment as having shown little improvement under treatment with tuberculin B. E. (Koch).

Improvement has taken place in nearly all cases, and is, in our opinion, of an order which exceeds obviously, that obtainable by any other form of treatment applicable to these conditions.

This statement was based on a period of treatment extending over but three weeks, hence it is evident that such a conclusion must be received with caution. What further work will reveal, no one can say, but the prospects are encouraging.

Due to the obvious objections that may be raised to the use of the term "defatted" antigen, Professor Dreyer has in later communications to the British medical press suggested the use of the term "diaplyte," signifying "washed through and through."

The National Institute for Medical Research has approved (*British Med. Jour.*, July 14, 1923) a plan whereby fifty beds in the Hempstead Hospital, twenty for men, twenty for women, and ten for children, will be given over to the treatment of tuberculosis cases with Dreyer's vaccine; the work to be under the direction of Capt. Douglas, bacteriological director of the Institute.

Industrial Physicians Meet

The American Association of Industrial Physicians and Surgeons, meeting in joint sessions with the National Safety Council, Buffalo, October 1-4, presented for discussion chiefly topics representing the socioeconomic phases of medicine rather than the clinical aspects of disease. Pleas were made for better uniformity in requirements of medical services under workmen's compensation,—the reduction of confusion by uniform regulations in thirty-seven states on railroad trains being cited as a typical example of possible simplification of codes.

Dr. C. W. Hopkins, of Chicago, reported on traumatic and industrial hernia from a sub-committee of the American Railway Association. The recommendation was not refusal to care for the hernia in industry, but for regulation that hernia results in predisposed cases and that record of pre-examination is the only safeguard in such cases.

The presidential address of Dr. C. E. Ford presented the strategic position of the industrial position and the onus he hears with regard to the maintenance of public health. Another expression from Dr. Ford, speaking

for the association, recorded their position that training for industrial practice belongs properly to post-graduate schedules rather than to pre-medical study.

Dr. Robert Carathers of Cincinnati spoke very sanely of the habits of twentieth century cliff dwellers as being productive of artificial life and artificial death. Adjustment (or simplification, if necessary) will be reflected in a reduction of the present high incidence of accident as well as of disease. Remedial care, whether industrial disability results from accident or slow poison, requires much on the part of the plant physician.

C. F. N. Schram, Beloit, Wisconsin, made a strong plea for social adaptability on the part of the physician in industry, and for giving full weight to the workmen's viewpoint. More specifically, Frederick W. Dersheimer of Cleveland, Ohio, urged the recognition of types and the full analysis rather than peremptory condemnation of the fractious or malingering patient.

An interesting reflex of some of the differences in viewpoint was brought out by a representative of the building trades of New York who reported —on the alleged basis statistical study of his particular group—a radically different accident curve and attributed the accidents themselves to causes rather than those usually assigned.

George M. Price, representing the garment workers, analyzed the physical status of 50,000 persons in this group. This represents perhaps the most extensive data from any specific industrial group. The results obtained and their strong preference for self-administered service deserve further study.

The final session of the meeting was held at the Buffalo City Hospital. The contribution of the members of the association to the program was supplemented by lecture-clinics by Frederick H. Albee, Udo G. Wile and George W. Crile.

Inspection of the new Buffalo City Hospital, particularly of the departments devoted to physiotherapy and heliotherapy, natural and artificial, was a valuable objective sign of the times in the development of services for complete rehabilitation after sickness or injury.

Officers for the ensuing year were elected as follows: L. A. Shoudy, president; D. B. Lowe, first vice-president; Wm. Alfred Sawyer, second vice-president; Dr. Kranz, Cleveland, secretary-treasurer; with Doctors Ford, Shafer, Watson, Geier and McKinstry directors for 1924-26.

An Unusual Insurance Home

The Maryland Casualty Company's Group of Buildings Includes An Administration Building, a Power Plant, a Print Shop, a Garage, and Laundry

IN MAY of the current year the Maryland Casualty Company celebrated the twenty-fifth anniversary of its organization, March 1, 1898, the occasion being observed in May because the weather is more favorable in May than in March.

This company started in the old Keyser Building, Baltimore, in two rooms containing eight hundred square feet, has grown till it occupied its Tower Building, Baltimore street and Guilford avenue, in 1905, and made its last move in 1921 to its present location in the Roland Park-Guilford suburban section of the city.

The home office force housed in the new building numbers 962. Its outside office force is 926 and its agents number 5,881.

The home office buildings are built on a twenty-five acre tract of land, leaving ample room for future additions as the future growth of the company demands. These buildings include an administration building where the office work of the company is done, a power house that supplies heat and electricity for the whole plant, a print shop where all the printing of the company is done and a garage for the accommodation of those employees who own automobiles, besides a laundry where the laundry work of the home office is done.

In addition to these buildings, there is a club house, with an auditorium that seats about 1,300 persons, having a fine Austin pipe organ, a rest room and dance hall for the women employees, and a game and smoking room for the men. It has a cafeteria that accommodates over five hundred at a sitting, a smaller dining-room for the officials of the company and guests, a library room, and sleeping accommodations for agents visiting the home office.

The pleasures and recreations of employees are cared for in grounds for baseball, courts for tennis lovers

and general outdoor conveniences for all. Hospital and clinical service is provided in New York, and Philadelphia, Atlanta and Baltimore and will extend this service more and more in the future.

Salvaging Men

Service is the watchword of the medical section of the Claim Division. Service in its broadest sense—service to our assured, service to the injured employees and service to society.

merely assisting nature in the repair of wounds or the healing of fractures. The handicapped must be returned to industry in a condition as near normal as modern science will permit. Thus, reconstruction therapy is making rapid strides in handling the industrially injured.

With complete rehabilitation in view, the Maryland Casualty Company has opened in New York, Philadelphia, Baltimore and Atlanta completely equipped surgical and rehabilitation clinics, with every appliance to restore the industrially injured to the maximum of physical perfection which modern science permits. These clinics are all centrally located with reference to the assured and are open during the entire working day.

When an injured man enters one of these clinics, antagonistic, in pain, distrustful, he is met by a carefully trained woman who re-assures him and gets from him a brief account of his injury.

In his turn he is ushered into the operating room where he is taken in charge by a surgeon. These surgeons are carefully picked for their personality. The suffering patient realizes as soon as our doctor touches him that he is in the hands of one who knows what is best for him, and proper treatment is at once carried out.

In close communication with the operating rooms, are modernly equipped x-ray rooms with the latest type of x-ray apparatus and fluoroscopes, this latter instrument enabling the surgeon to look directly at an injured bone or joint and, without the delay necessitated by the taking of a picture and developing it, can at once institute proper treatment. Photographs for permanent record are made later.

Responsibility does not end when the broken bone has united and the wound has healed. When active treatment at the hands of the surgeon is

Auditorium of Clubhouse of the Maryland Casualty Company.

When we look back at the days before the advent of workmen's compensation laws and remember the human wrecks doomed to poor houses, or to lives of suffering through physical disability caused by the lack of proper medical care, a thrill at the changed conditions is experienced.

The Maryland Casualty Company now has a corps of approximately one thousand, eight hundred appointed surgeons carefully picked for their skill, who are at the immediate call of any of its assured. The family doctor cares for illnesses but the man with a broken thigh or a fractured skull or a damaged eye is given treatment at the hands of the trained specialist. The company placing at the command of the industrially injured, surgical service at the hands of eminent specialists which they could not possibly pay for at their own expense. Responsibility extends further than

over, the patient is placed in the care of skilled physiotherapists. There, injured joints are treated in the most approved electric bakers and manipulation is given with the idea of breaking up adhesions and giving nature opportunity to bring about a restoration of function. Devices are made for applying intense heat locally, thus relaxing damaged tissues and permitting the blood to circulate freely, a skilled masseur rubs out the soreness. Electrical apparatus through which high voltages of electricity are forced through damaged joints, generates an intense heat within the joint without the slightest discomfort to the patient.

The clinics are all equipped with complete electrical apparatus for the administration of galvanic, faradic and sinusoidal currents, especially valuable in treating injuries to the peripheral nerves. There is also complete installation of modern apparatus for the re-education of muscles and joints, weakened by disuse and stiffened by adhesions. To watch a patient undergoing a course of treatment with this apparatus and to see his interest in his graphically recorded progress toward recovery is most interesting. By such mechanical aids and with such incentives workers are restored to their old occupations without disability who otherwise would have remained burdens upon society. The results have been most encouraging and have shortened disabilities, greatly lessened the permanent handicap.

Every person accepted for employment by the Maryland Casualty Com-

pany is examined thoroughly by our physician. This examination covers the nose, throat, ears, eyes, neck, heart, lungs, kidneys, knee reflexes, and blood pressure. Many applicants are accepted with minor impairments which are cared for by the employee service division and in nearly all instances the impairments are remedied. There is provided a specially equipped dispensary, a rest room, and an examination room. From twenty-five to sixty patients are treated each day for minor conditions such as headaches, sick stomachs, lesser injuries, etc. All major work is sent to the Baltimore clinic. Every morning an absentee slip from every department is rendered to the employee service

Mechanotherapy room, Philadelphia Clinic.

cants seeking employment. An analysis is made of the various positions throughout the company, comprising a description of duties and the qualifications needed for one to satisfactorily carry on the responsibilities of

the respective positions. Every employee is periodically rated in seven specific qualities by two or more supervisors, to whom his ability and fitness for the position he is holding is best known. This data is added to each individual's record and is considered in salary increase and promotion, applicants favorably considered for employment are required to pass a thorough physical examination before final acceptance.

The company provides for their employees a disability allowance which increases according to length of service. After one continuous year's service, they are covered, without cost by life insurance, the principal of which is figured on a percentage basis according to length of service. Effort is always made to place employees in positions according to their preferences and fitness, in the belief that contentment in one's work is an important factor in maintaining health and happiness.

Employees' Club House

The club house of the Maryland Casualty Company is a large, modern and very beautiful building, erected solely as a place for the pleasure and use of the company's employees. In the ball-room three hundred couples can dance without difficulty. During the lunch hours this room is the main lounge for the girls. It is furnished with comfortable sofas, arm chairs,

Social Hall for the use of employees.

division from which a visiting sick list is made. All three day absentees are visited and in many instances two and one day absentees.

Before the sick visiting was put into force, when an absentee was reported we never knew if conditions were just as reported. Now we see and understand the necessity of a day at home. A Ford sedan is placed at the disposal of the visiting nurse to make these visits and to take any employee home who has become ill while at work.

Personnel Work

In the personnel and employment office is recorded a complete personal history of every employee, his qualifications, his preferences in the way of work, and his educational desires; similarly, there are recorded the qualifications of all appli-

X-ray and Physiotherapy room.

Operating room of the Baltimore Clinic.

and rockers. A piano and victrola are provided, also many new and "jazzy" records. The girls come into this room, some to sew or read, some to gossip, and a great many to dance; in fact, dancing is by far the most popular form of entertainment. The girls nearly always dance with each other, although men are allowed in the hall.

There is an excellent library in the club house with standard works, histories, biographies, and novels of every description. Five cents entitles anyone to take out a book and keep it for two weeks; a fine of two cents a day is charged if kept overtime. This nominal charge enables the librarian to keep track of the books and to purchase the new "best seller." The library is popular and well patronized, an average of one hundred, fifty books being always in circulation. Current magazines are provided in the reading room but not for circulation.

Corresponding with the girls' lounge is the men's smoker—a beautiful, spacious, and comfortably appointed place on the second floor of this building, where smoking, card games, chess, and reading are the forms of diversion indulged in by the men.

Another feature of the club house is the auditorium. This hall is one of the finest in the city and has facilities for moving pictures and splendid acoustics. Lectures and meetings for the employees are held in the auditorium; also "home talent" occasionally presents a play.

Last but not least there is the caf-

eteria. This is a drawing card for all. The motif of the cafeteria is white tiles with green stripes, giving a cool and clean effect. There are one hundred, twenty-five white marble-top tables with places for four at each table. Every one patronizes the cafeteria as it is out of the question to go down town for a meal, and then—why go down town, when an excellent dinner, consisting of meat, the choice of two vegetables, bread and butter can be had for twenty-three cents?

Adjacent to the cafeteria is the club store where many little necessities can be bought, and where a great trade is carried on in candy, peanuts, cigarettes, etc.

The Story of Johnny Dontcare's Tooth

"The Story of Johnny Dontcare's Tooth" is told in a set of 23 stereopticon slides recently prepared by the Toledo Public Health Association for use in its campaign of health education, in which lantern slides have an important part. One of Johnny Dontcare's perfectly good teeth went bad because of the usual cause—inattention. The slides, all of them in colors, and all but four illustrated, show just what happened to the tooth, and then tell how the loss of the tooth might have been avoided by proper care and by at least two visits a year to the dentist. By their combination of brief captions in simple words with careful drawings and amusing cartoon illustrations, the slides tell a consecutive story without the neces-

sity for a lecture or spoken address, yet they could be used to accompany a talk on dental hygiene before any audience. The Toledo Public Health Association, 401 Produce Exchange Building, Toledo, Ohio, has arranged to make sets of these slides available to other health agencies and workers at cost price.

Dental Clinics Serve Half a Million in New York Schools

Dental services, limited to children in the lower classes, more particularly 1-A and 1-B grades except for emergency cases, have been much more effectual since the twenty clinics have been established in the schools instead of detached centers.

The main activity of the dental department is preventive work, as applied to children, this means as well such reparative work as will preserve the six year molars. Operative work on pulpless teeth has been entirely eliminated. Modern equipment, including a new type of chair, electric engine and sterilizers, has been installed in most of the clinics. The dental hygienists have been supplied with a new type of prophylactic instrument, designed by Dr. H. W. Gillette of the Columbia University Dental School, which obviates, it is said, injury to the gums.

The Board of Health appointed a Dental Advisory Board of twenty-one members to study the problems of the clinics and cooperate with the Bureau of Child Hygiene in developing the best procedure and extending the work.

League of Minnesota Municipalities

Reports on Health

THE following report on health conditions in Minnesota is the report made by O. E. Locken, chairman of the Committee on Public Health made to the League of Minnesota Municipalities at the meeting held in Faribault in June. The report was fully approved and made the basis for the health emphasis of the ensuing year. The report follows:

To promote health more effectively, this committee suggests that the League of Minnesota Municipalities shall go on record as supporting the following principles:

- I. The health of a community, as with every other civic service, is purchasable not only by money, but by cooperative effort.
- II. That the attitude of the public towards public health work is not progressing with the same rate as the success of the efforts of preventive medicine itself.
- III. That the present status of local municipal health laws is one of the factors in this failure of the public to appreciate the power of preventive medicine.

To correct these conditions, and to further insure the progress of public health work, the League shall go on record as supporting the following plans:

- (A) The local Municipal Health Boards shall be made uniform throughout the State, the Board consisting of five members: (1) The health officer, who shall be a physician, and who will act as chairman. (2) The Chief of Police. (3) The city engineer or street commissioner. (4 and 5) To be selected from public at large.

In such a board, the health officer could confine his attention and responsibility to controlling infectious diseases, and in general to carrying out the laws and orders of the State Board of Health.

To the chief of police would be referred all problems of nuisances, which now the public are in the habit of placing on the health officer. This would be a means of eliminating these inquiries to the State Board of Health, which now make up fifteen percent of that Board's correspondence.

To the city engineer or street commissioner, all problems of public sanitation would be referred. The conditions of streets, alleys, sewerage, drainage, water supplies, etc., would come under this division, thus insuring adequate attention to the same.

The fourth and fifth members to be chosen from the public at large with the recommendation that at least one

of these be a woman, would contribute their interests chiefly in city clean-up campaigns, nuisances, milk control, maternity and infant welfare and child welfare, school and city nurses work and educational health work in general.

Such a uniform and standard Health Board would focus the attention of the public on the modern demands of community health.

(B) With the increasing centralization of people in cities, and a proportionate decrease in rural population, the problem of garbage, manure and waste disposal becomes an important study. Success of fly control is dependent upon proper collection of these products. With the increasing tourist trade in Minnesota, the public is entitled to the assurance that every city has adequate methods of protection from food and waste matter. With this broadened viewpoint, we recommend a modification of the present general State law, which would compel standard city and village ordinances dealing with collection and disposal of garbage, manure and waste products throughout the state. Such a law would compel the collection of garbage in suitable receptacles as heretofore in city or village, and its disposal a definite and specific number of times per week, varying with the season of the year and with the zoning of the city into business and residential sections. Such a definite, specific state law would give the local Health Boards power to act where they are now limited in jurisdiction by inadequate local charters.

(C) The municipalities of Minnesota should be encouraged to pass uniform legislation controlling the milk supply of the state. To insure careful handling of the problem it is recommended that the State Board of Health prepare model milk ordinances applicable to the various communities and urge the passage of the same as ordinances in every municipality in the state.

(D) It is recommended that the municipalities be encouraged to establish laboratories in connection with the health and engineering departments for the purpose of examining the water and milk supplies, the tuberculin testing of cattle of the community, to do meat inspection and to make examinations of food in general as might be required locally. This work to be done under the general supervision or in accordance with the requirements of the State Board of Health.

(E) We recommend that the habit of financing the local health officer's work on a fee basis be abolished, and that fixed salaries for the same, proportionate to the size of district, be granted. The fee basis used at present often places the health officer in an embarrassing position by the com-

mon statement that he is seeking the fees which his interference with other people's violation of the law brings him.

(F) With the knowledge gained in the World War that 37 per cent of the young men of draft age in the United States were rejected because of physical defects, we are astounded in the realization that no effort has been made to combat this terrible indictment of our neglect of the health of children of school age. To make progress against this condition, we believe that the attack must be made at the source of the trouble. To insure success at all, and to make this what it should be—a state problem—we recommend that special state aid be given to every school district, proportionate to the number of children, for the purpose of holding annual or semi-annual medical examinations and inspections of all school children. Such examinations and recommendations are to be recorded on uniform reports standardized by the State Board of Health, and kept on file in the records of the local school; the statistics from these to be filed with the State Board of Health; the expenses of such examinations to be controlled and fixed by State law.

It is further recommended that in schools of cities and consolidated districts where the field is large enough to warrant employment or full time school nurses, these appropriations could be used to apply on the expenses of the district for such a nurse. In the smaller outlying districts the medical examinations by local physicians would be more practical.

Conclusion

It is the opinion of this committee on Public Health that the success of public health work will be greatly advanced by concentrating our efforts in making our municipal health ordinances uniform throughout the State. Disease makes no distinction between individuals or communities, and therefore the laws governing the control of disease should find no exception, by a presumption that local conditions require a variation from fundamental facts.

Investigation as to the avenue of transmission in a small typhoid epidemic in Newman, Douglas County, Illinois, disclosed the cause to be a typhoid carrier who gave a history of the disease fifty-three years ago. Illinois Health officials report this as the oldest, in point of typhoid carrier state, of any that has come to their notice.

Activities of the National Child Labor Committee

THE National Child Labor Committee which was organized in 1904 and incorporated in 1907, and which has been fighting child labor for about twenty years, may legitimately be classed as a "health organization" although the word health does not anywhere appear in its name.

One of the most serious evils of child labor is its effect upon the physical well-being of those engaged in it. From the time of its foundation the committee has recognized this fact as may be seen in a section of the Act of its incorporation which is given below.

Throughout its entire history the Child Labor Committee has emphasized the health aspect of child labor. For example, within the past few years specialists have been engaged simply to study and measure scientifically the facts regarding the results which premature employment has upon the bodies of children. Of course the health phase is only one among many phases involved in the problem upon which the Committee has been working. The effects upon the minds and morals of the children seem to many quite as serious as the effects upon their bodies.

The functions of the Committee are embodied in Section 2 of the Act of Incorporation. This Act states that the objects of the National Child Labor Committee shall be: To promote the welfare of society with respect to the employment of children in gainful occupations; to investigate and report the facts concerning child labor, to raise the standard of parental responsibility with respect to the employment of children; to assist in protecting children, by suitable legislation, against premature or otherwise injurious employment, and thus to aid in securing for them an opportunity for elementary education and physical development sufficient for the demands of citizenship and the requirements of industrial efficiency; to aid in promoting the enforcement of laws relating to child labor; to coordinate, unify and supplement the work of state or local child labor committees, and encourage the formation of such committees where they do not exist. In accordance with the provisions of this Act, the National Child Labor Committee

has investigated problems which are closely related to child labor, viz. education, recreation, juvenile delinquency, health and mothers' pensions.

The officers of the corporation consist of a chairman, two vice-chairmen, a treasurer, a secretary, and a board of twenty-five trustees.

The office staff is as follows: general secretary, field director, publicity director, membership director, and research director. In addition, a staff of specialists as agents for the Committee are maintained for investigation in various fields.

The non-corporate membership of the National Child Labor Committee consists of about 15,000 members and contributors.

The national headquarters of the Committee are at New York City. Local membership state committees under the direction of state chairmen are maintained in the following states: Alabama (Montgomery), California (San Francisco and Los Angeles); Colorado (Denver); Michigan (Detroit); Minnesota (Minneapolis); Mississippi (Okolona); New Hampshire (Hanover); Tennessee (Nashville); Washington (Seattle); Wisconsin (Milwaukee). Besides these, the committee is affiliated with State Child Labor Committee and other voluntary welfare agencies.

The services of the Committee may be defined as administrative, field work, publicity, membership, and research.

The administrative department supervises and coordinates the work of the departments and all field work.

The field work department makes state and local investigations with reference to child labor and child welfare in general, for the purpose of standardizing laws and administration and establishing children's codes, these surveys being made at the request of the local organizations and in cooperation with them.

The publicity department publishes *The American Child*, a monthly bulletin and an office bulletin, or weekly "house organ", issues special pamphlets and carries on publicity campaigns in magazines and local newspapers.

The membership department promotes membership in the Committee as a national organization.

The research department studies, compiles, and disseminates information and statistics, with special reference to legislation; collects reports from state officials; collects abstracts from foreign publications, and puts material already in the library in usable form.

During 1922 the Committee published a book "Rural Child Welfare" which is based on a study of rural child welfare conditions in West Virginia. The Committee conducted similar intensive state surveys in Alabama, Oklahoma, North Carolina, Kentucky and Tennessee. The Committee makes local investigations of certain industries and gives legislative aid in drafting and lobbying for child welfare laws. During the fiscal year of 1922, the members of the field staff have been engaged in Alabama, Iowa, Kentucky, Michigan, New Jersey, New York, Ohio, Virginia, and also in Nebraska, North Carolina, and Rhode Island. Calls from sixteen states for general surveys, special studies or legislative assistance were not met because of limited staff and funds.

Malaria and the Railroads

The results of a malaria survey of the Missouri Pacific Railroad lines south of St. Louis brought out the fact that during the last twenty-three years the number of employees given hospital treatment for malaria by the Employees' Hospital Association averaged more than one thousand annually. This number constituted 35 per cent of all hospital admissions and 45 per cent of all sick cases. For the same period injuries and surgical cases combined totalled only 75 per cent of the malaria admissions. In one hospital over 50 per cent of all medical cases were malarial, and in addition four thousand employees received out-patients treatment for malaria each year.

The academies of medicine in the larger cities of Ohio are formulating committees from their orthopedic contingents for the purpose of supporting the new series of orthopedic clinics to be held under the joint auspices of the medical profession, the State Department of Welfare, the State Department of Health, and the Ohio Society for Crippled Children.

Buffalo Meeting of National Safety Council

MORE than three thousand delegates registered at the meeting of the Twelfth Annual Congress of the National Safety Council held at Buffalo, October 1-5. Physicians, surgeons, insurance experts, plant managers, psychologists, and engineers in representative groups bent their collective efforts toward the control of the factors involved in the waste through accident of 25,900 lives during 1922.

Whether the cost of accident is to be a charge upon society as a whole, upon industry, or is to continue to bear chiefly upon the individual sufferer, or whether it is to be attributed to the indifferent employer, the careless workman, or the type of individual who is termed the habitual accident maker is of basic consideration. The economic waste involved is of the first magnitude and accounts for the remarkable showing of the safety council group.

Constituted at first entirely of business groups—men of action with power and vision to enforce certain protective codes in industry—the movement has grown until it is one of scientific method, exhaustive inquiry and highly technical investigation. Sectional meetings of the Congress were particularly interesting. The Chemical and Rubber Section continued for an indefinite period, the powers of their committee appointed to investigate benzol poisoning, whose first report read at this meeting constitutes the most productive piece of work as yet undertaken in this important field.

A safety code for chemical laboratories was also offered in this section and mechanical methods of handling advocated to reduce accidents to a minimum.

Safety from the viewpoint of preventive medicine was brought out in many sections, especially in the joint general meetings of the Council with the American Association of Industrial Physicians and Surgeons, but the insurance group contributed much pertinent information in this regard and a concrete example of constructive effort was detailed in Leland E. Cafer's outline of the proposed intensive study of industrial diseases and accidents about to be undertaken by the New York State Department

of Labor with the cooperation of the United States Public Health service and the Public Health Committee of the New York Academy of Medicine.

The resistance to the universal efficacy of the safety idea is the impassé of ignorance which halts progress in other lines.

The 1923 Congress was particularly effective in its educational effort. The Pageant drama "Adventure" written by Thomas Woods Stevens of the department of dramatic art, Carnegie Institute of Technology, and presented by his students, differs from the dread fears of inhibitive psychology which permeated all of the earlier safety propaganda and ideals the "safe" individual as the "constructive" and "productive" individual. It is by selection—intelligent personnel work—and by educational effort with the young in our schools and during the initiative period in industry that safe concepts are fostered and safe habits enjoined. Nor were employes' activities overlooked. So the Safety movement finally emerges as a coordinating agency and its tremendous influence takes added interest as a sociological phenomenon.

The trend of some of its newer activities will be watched with interest.

An international interest was achieved at this meeting by the introduction of Sir Thomas Oliver, as chief speaker of the Congress, distinguished industrial physician and former chief of the Medical Staff of the Industrial Bureau of the British Home Office.

The remarks of Sir Thomas summarized his impressions gained from a rapid survey of manufacturing plants in the leading cities of the United States. Everywhere he notes better organization and more concentrated attention upon hygienic and health problems. Theoretically, the British Office has done more, but in practice the American executive puts more energy into the program and finds less resistance. The tragedy of the British situation is the utter stagnation that brings to fore the health evils, rather than any dangers inherent in industry itself.

He concluded his remarks with an outline of foreign study on the diseases of occupation and the result-

ing reduction of health hazard.

The final executive session of the Congress resulted in the election of the following officers:

President, L. A. De Blois, Wilmington, Del.; vice presidents, C. B. Auel, East Pittsburgh, Pa.; Marcus A. Dow, New York; George T. Fonda, New York; H. A. Renninger, Allentown, Pa.; and David Van Schaack, Hartford, Conn.; vice president and treasurer, Homer E. Neisz, Chicago.

Executive committeemen, C. B. Auel, East Pittsburgh, Walter G. King, New York, C. E. Pettibone, Boston, L. A. De Blois, Wilmington, George T. Fonda, New York, Henry A. Renninger, Allentown, Dawson R. Hall, New York, Julian H. Harvey, Kansas City, Robert E. Herdegen, Walkerville, Ont.; Colonel C. M. Hinkle, Chicago, Homer E. Neisz, Chicago, A. D. Risteen, Hartford, Herbert A. Rowe, New York, R. B. Stoeckel, Hartford.

Representing sections: David Van Schaack, Hartford, chairman street and highway safety; A. W. Whitney, New York, chairman education section; James P. Barnes, Louisville, Ky., chairman electric street railway section; F. P. Walker, Detroit, Mich., chairman ice and refrigeration and taxicab and delivery section; A. L. Watson, Niagara Falls, chairman chemical section; H. W. Moses, Boston, chairman public utilities section; Fred Metcalf, Saint Paul, chairman steam railroad section.

Doctors With Wings

The Australian Inland Mission, serving a vast stretch of hundreds of miles of sparsely populated country, rich in flocks and wool but with no direct train communication between its towns, has been instrumental in establishing six cottage hospitals in various community outposts throughout the Australian bush. It is intended that these hospitals shall be supplemented by aerial depots with flying doctors whose united radius of action will cover the whole of the continent while every section of the "outback" will be linked up by a system of wireless. Were the romance of pioneering and the miracles of modern science ever united in a more delightful fashion!

Back-Yard Playgrounds

THE increase of motor car traffic brings with it an ever increasing record of accidents to children.

We are told that "familiarity breeds contempt" and it would seem that children are becoming less apprehensive of danger from auto vehicles, despite all our safety first educational efforts.

We cannot stop the use of motor vehicles but we can minimize the number of children killed or maimed by them. Experience proves that all of the children in a district will not walk several blocks to a playground or to a play street. In fact, it is not unusual to see children playing on the street in front of a playground or outside of the barriers in a play street.

You cannot close every street and were you to put a playground on every corner you would still find children playing in front of their own doors and dashing out into the street after the elusive ball. We cannot take the ball from them nor prevent them from playing tag and the other health-giving games of childhood.

We cannot deny them their God given right to robust and happy play, but we can protect them and it is our duty to do so. We spend millions to protect life and property by increasing the efficiency of our police and fire departments and our health and hospital service, but when it comes to the child on the street the knife of the budget parer sinks deep into the asked for appropriation. We are more interested in low tax rates than in the little white coffins that pass through our streets. We forget that in the vigor and happiness of the child lies the safety and progress of the nation. We are not impressed with the fact that more than one-third of all the boys drafted in the late war were rejected because they were physically unfit to fight.

Every municipality owes it to its boys and girls and to the nation to give them a chance to become physically fit through opportunity for untrammelled play.

"The solution of the problem is simple," according to Harry H. Moore, director of Parks and Public Property, of Jersey City, N. J.

Turn the children out through the back door instead of the front. In every square block there is an open space in the rear of the houses, the combined backyards. This open space must always remain open and, where the buildings consist of large apartment houses, the open space is fixed by law. These yards are usually ill-kept and surrounded by fences. The plan is to knock down the fences, cleaning the entire space, planting here and there a poplar, Ailanthus, or other quick growing tree, a border of privet hedge or a few ball privet, with here and there a little patch of grass or flowers and you have turned the unsightly and insanitary yards into a delightful breathing spot. Now in the center a little summer house or pergola with a sand box, on either side a six swing outfit, baby swings, a couple of slides, and a basket ball standard or two, and you have a delightful and protected playground for all of the child inhabitants of that square block and all for the cost of a medium low priced automobile.

The mothers working in the rear rooms have the children under their eyes all the time and know that they are safe from the dangers of the street and at the same time they are enjoying all the activities afforded by well planned arrangement for their use and protection.

In the Jersey City plans for the installation of several of these backyard playgrounds are now actively under way.

Wide Survey Shows an Increase in Cost of Food

The Bureau of Labor Statistics of the Department of Labor has completed a survey of food costs in fifty-one of the leading cities of the United States. The highest per cent was recorded in Philadelphia, the increase in the cost of living being 4 per cent. Baltimore, Bridgeport, Butte, Mont., Cleveland, Detroit, Los Angeles, Louisville, Milwaukee, Minneapolis, New York, Norfolk, St. Paul, San Francisco and Washington showed an increase of 1 per cent. A decrease of 1 per cent was shown in Memphis, Mobile, Newark, New Orleans, Rochester, and Springfield, Ill. The average increase for the year ending May 15, was 3 per cent.

Hospital and School Work Allied in Alaska

The Bureau of Education of the Department of Interior has announced the increase in the number of teachers in Alaska from 133 to 144.

The schools are located in seventy-five small villages and are under the direction of a superintendent with headquarters in Seattle. The schools are established as the centers of small native villages and the teachers must act as guides, nurses, advisers in civic as well as social affairs, and in solving the economic problems and are instrumental in saving thousands of the Alaskan Eskimos and native Indians from starving each year.

Records show a wonderful work is being done in the hospitals maintained by the Bureau of Education also, seven physicians and seventeen nurses being on constant duty. The hospital at Juneau also receives native girls for training as nurses. Simple remedies and full instructions as to their use are sent to all teachers in the schools in the remote and scattered villages over the land.

Neglected rear door yards of city tenement districts can with a little thought and a very slight expenditure be transformed into life-giving and life-saving areas. This shows a typical transformation so effected in Jersey City, N. J.

LATE HEALTH DECISIONS IN THE COURTS

BY DOROTHY KETCHAM, UNIVERSITY HOSPITAL, ANN ARBOR, MICH.

WHERE an injury to an employee caused an aggravation of a prior diseased condition resulting in total incapacity, the employee is entitled to compensation for total disability under the workmen's compensation act by decision of the Supreme Court of Errors of Connecticut, July 7, 1922.

The following facts were stated in the finding and award: The plaintiff was injured by a blow on the right shoulder joint, arising in the course of and out of his employment. This injury incapacitated the plaintiff to work from August 21, 1920 to May 31, 1921. The average weekly wage of the plaintiff was \$15.05. Previous to August 20, 1920, the plaintiff was suffering from a tuberculous and syphilitic condition which had become localized in the right shoulder joint, resulting in a complete ankylosis. Said condition had become stable and would not have materially progressed without some new exciting cause, and it did not disable or incapacitate the claimant for his work as a laborer. The blow immediately "lighted up" the tuberculous and syphilitic condition previously existing and produced a condition incapacitating the plaintiff to work. If the plaintiff had been physically normal and in perfect health, the injury probably would not have incapacitated him for more than a short period of time. Public Acts 1919, C 142, sec. 1, amending Gen. St. 1918, sec. 5341 was cited as providing that, in case of the aggravation of a disease, compensation is to be allowed only for the portion of the disability reasonably attributed to the injury, but, as this provision was part of a remedial amendment bringing occupational diseases within the act, the court held that it refers only to cases involving industrial diseases.—*Bongialatte v. H. Wales Lines Co.*, 117 A. 696.

THE term "injury" according to the Supreme Court of Ohio, April 25, 1922, does not include those diseases which are contracted, as distinguished from diseases which are occasioned by

or follow as a result from physical injury.

The death was occasioned by typhoid fever, the claim being made that Cross died as a result of injuries received in the course of employment. The case turns on the definition of the term "injury." In the opinion of the Court "we are unable to comprehend how this court in the light of the differentiation which the Constitution makes between injury and occupational disease, can arrive at the conclusion that, without specifically including or excluding either, it was the intention of the legislature, in following the language of the Constitution, to include under the term "injury" disease generally, and at the same time exclude one form of disease. "In view of the constitutional interpretation and the Compensation Law, the Industrial Commission has given the term 'injury' an interpretation which excludes diseases which are contracted, as distinguished from diseases which are occasioned by or follow as a result of some physical injury, and in view of the fact that to interpret the term 'injury' as including diseases generally would enlarge the scope of disabilities . . . we hold that, if the scope of cases compensable is to be extended, it should be done by unambiguous legislative enactment rather than by judicial construction. For construed to include typhoid fever contracted in the course of employment, it may as well include influenza, pneumonia, tuberculosis, smallpox, ordinary colds, rheumatism and practically every disease which may be contracted in the course of employment, and the Workmen's Compensation Department will become a health and life insurance department."—*Industrial Commission v. Cass*, 136 N.E. 283.

New York to Study Industrial Diseases and Accidents

An intensive study of industrial diseases and accidents is to be undertaken by the New York State Department of Labor based upon data affecting 1,225,000 workers engaged

in the seventy thousand or more industrial plants in the state.

This proposed study was announced in an address by Dr. Leland E. Cofer, director of the division of public hygiene of the New York State Department of Labor at the Twelfth Annual Safety Congress of the National Safety Council at Buffalo, Oct. 1 to 5.

Dr. Cofer said that the department proposed to study conditions as they exist at the present time so that the results of any improvement may be properly appraised in the future. Every possible advantage will be taken to carry out educational activities for the purpose of teaching the worker how to work as well as how to look after his personal health and safety, he said:

"The industrial hygiene division of the state of New York examines annually approximately five hundred sets of plans of devices for the removal of obnoxious dust and fumes from workrooms," Dr. Cofer said. "It is proposed to analyze the results of this experience.

"It is also proposed to make a special attempt to enlist the interest of the medical profession in the state of New York in recording and reporting not only the specific industrial diseases, but other diseases which may be associated with industry.

"It is all-important that the proposed intensive study should be based on statistics as to the present status of industrial diseases in the state of New York and as stated, before appeal is made to the medical profession to give their aid, although it is appreciated that the answering of questionnaires on the part of busy practitioners in medicine is a downright hardship.

One of the most important points brought out by Dr. Cofer is the fact that in the endeavor to carry out this intensive study cooperation of the organized public health institutions, the medical profession at large, and the business and labor interests has been enlisted.

Twenty-two states now require the physical examination of every child applying for an employment certificate. Eight others and the District of Columbia allow the certificate-issuing officer to require an examination when he is in doubt as to the physical condition of the child. In eighteen states there is no legal provision for examination, when a child first enters employment.

SANITARY AND HYGIENIC ADVANCE

Dysmenorrhea in Industry

Sturgis finds that the great majority of women suffer no appreciable lowering of efficiency during the menstrual function. A study of 2,077 consecutive examinations of women employed in a large department store has shown that 65 per cent had no menstrual handicap; 30.6 per cent had only a slight handicap; and 4.4 per cent were seriously handicapped. The author believes that the attitude of the industrial hospital is most important and that by education and proper management of the hospital much can be done to overcome lowered efficiency. The disability of the few should not be charged against the great majority of women in industry whose lowered efficiency as a result of menstruation is negligible. (*J. Indust. Hyg., June 1923, v. 2, p. 53*).

Bacterial Analysis of Sugars

Papers by Kendall and Kendall and Yoshida (*J. Infect. Dis., May 1923, 32, 5*) in a series of articles by the senior author and his co-workers describe means of identifying and measuring small amounts of carbohydrates in mixtures, by bacteriological methods. One one thousandth of one per cent levulose can be detected by the change in pH produced by *Bact. coli*.

A standard series of microbes makes it possible to isolate or identify one or more sugars in an unknown mixture. The essentials for the detection of small quantities of sugars alone or in mixtures are, microbes of known fermenting powers, a set of carbohydrates of known purities, and standard phosphate solutions of known hydrogen-ion concentration.

Sterilizing Milking Machines

Bacterial count obtained in comparative tests made with milking machines sterilized in hot water, and others sterilized in a chlorinated lime solution, favor the heat method of sterilization according to L. H. Burgwald, author of "Cleaning Milking Machines" (*U. S. Dept. of Agriculture, Farmers Bul. No. 1315*). The average bacterial count of 74 samples

taken at 13 farms using various methods other than heat for the sterilization of milking machines was 257,900 per c.c. Two hundred sixty-one samples taken at the same farms when the heat method of sterilization was used had an average bacterial count of 19,300 per c.c.

"Samples of machine-drawn milk taken at a total of 20 farms using this method had an average bacterial count 13,750 c.c. for 622 samples, and 376 of the samples had a count of 10,000 per c.c. or less." The effect of heat on the rubber parts of the machines has not been fully determined but it appears to be but slightly if any more detrimental than other methods of sterilization.

A series of pictures shows the method of cleaning which consists in drawing through the machine by vacuum, clear water, water containing soap powder and at the same time brushing teat cups and tubing, clear water again; the long milk tube with claw and teat cups is placed in water which is then heated to 160-170 degrees F. The vacuum line should be cleaned every two weeks by drawing hot water containing washing powder through it. The moisture trap is cleaned thoroughly every day and twice each week the machine is taken entirely apart and washed with a brush.

Milk-Borne Epidemic of Septic Sore Throat in Portland

The epidemic in Portland, Ore., reported on by Benson and Sears, (*Journal A. M. A., June 2, 1923, lxxx, 22, p. 1608*), which included 487 cases of septic sore throat, with twenty-two deaths, occurred almost exclusively among the customers of a single raw-milk dairy. All but one of the patients who died had drunk this milk. Prompt detection of the cause of the epidemic and equally prompt control of the milk supply by heating were made possible by complete cooperation between the clinicians, the city health bureau and the dairy management, and resulted in checking further extension of the epidemic within twenty-four hours after the suspicion of a milk-borne epidemic was first brought to the attention of

the health bureau. Similar strains from hemolytic streptococcus were obtained in almost pure culture from the inflamed udder of a cow of the herd, from one milker's throat, and from the throats of numerous septic sore throat patients and contacts. All these strains were shown to be of the human type. It is probable that the milker in question infected the udder of the cow, producing purulent mastitis; that, on one or more occasions, this cow was milked in with the herd, and that the massed infection thus produced resulted in the epidemic. This cow's udder had both human and bovine strains of hemolytic streptococci. One quarter, containing a human strain, had a massive mastitis indistinguishable grossly from garget; another quarter, having a bovine strain, was only slightly consolidated.

Feeding Garbage to Hogs

The arrangement for garbage disposal in Sacramento, Calif., is as follows: The city collects and delivers garbage at the hog farm—an average haul of two miles; the contractor supplies the hogs which must not weigh less than eighty pounds at the time when delivered at the farm. The contractor runs the farm and when the hogs are sold pays the city the sale price for one-third of the net gain of the hogs in weight. Material not eaten by the hogs is buried.

It is estimated that the city will make a net profit of \$1,200 a year on the contract, and in addition it saves \$13,500, the expense of incineration in the past. (*Eng. News-Record, April 26, 1923, 90, 17, p. 742*).

Length of Working Week

The length of the working week of the average American employee has declined thirty-six minutes in the last two years, according to a statement issued by the National Bureau of Economic Research. Employers engaging finance, public and professional service require the longest hours, the average being slightly more than an eight-hour day for a seven-day week. Farmers and retail merchants each require over fifty-three hours a week of their employees, while the industrial group including building and construction, finance, public and professional service, printing establishments, and factories making textiles, clothing, and leather goods usually call for forty-eight hours a week from their employees. Longer hours are usually required by smaller firms.

New Method of Disinfecting Hides

Smyth and Pike in testing iodine as a disinfectant for anthrax-infected hides and skins, (*Am. J. Hyg.*, May 1923, iii, 3, p. 224) on a laboratory scale, found that either iodine vapor or a solution in water or carbon tetrachloride or carbon tetrachloride and gasoline, produced most satisfactory results in two hours. The former method consists in placing the hides in a chamber which by pressure and exhaust is filled with iodine vapor generated outside the chamber. The temperature within the chamber is maintained by steam coils thus preventing the deposition of the iodine. Vapors from the chamber are cooled and condensed in a baffled box which recovers much of the iodine. After the hides have been gassed they are given a short soak in thiosulphate, rinsed and placed in the lime vats.

The liquid disinfections are carried out in the ordinary tannery tumbler. A bath in thiosulphate follows. The iodine solution may be used over and over again; being brought up to strength (1 part skin to 9 parts of iodine) by adding iodine from time to time and the iodine removed from the skins by the thiosulphate is easily recovered.

Iodine is of course quite expensive. The liquid methods are in this respect more desirable and the carbon tetrachloride best of all. The expense of this latter chemical can be reduced by mixing with it some light hydrocarbon.

Tuberculin Test for Cattle

Experiences in obtaining and maintaining a tuberculin-free herd of cattle have been related by Dahlberg (*N. Y. Agri. Exp. Sta. Bulletin No. 496, Jan. 1923*). The original Bang method was followed in the station herd.

How accurate and reliable has this tuberculin test been in the Station herd? In the tuberculin herd maintained from 1901 to 1905, it was not especially accurate, as it gave a false report in 11 out of 64 tests. The tuberculin tests selected out all the tubercular cattle from the general herd in two years, namely, 1900 and 1901, which is a remarkably fine record. In 1904 and 1905, it showed two other cows to be tubercular and lesions were found in their bodies. In 1915 and 1919, two animals that reacted were probably not tubercular, while in 1922 the test on one cow contradicted itself. Since the healthy herd was established in October, 1901, it has been subjected to 816 tuberculin tests. The test showed six animals to be tubercular which were later proved tubercular. Since 1905,

the tuberculin test has shown three animals as tubercular which displayed no lesions of the disease. Three possible errors in 816 tests is as accurate as one could ever expect such a test to be.

The author summarizes as follows:

The tuberculin test has been invaluable in securing and maintaining a tubercular-free herd at this Station. The test has not been perfect, but it has been so accurate that by its use a tubercular herd was freed of the disease and a healthy herd maintained for 17 years without one demonstrated case of tuberculosis.

Biology of Sewage Purification

In reporting on the work of the sewage substation of the New Jersey Agricultural Experiment Station and the New Jersey State Department of Health, Rudolfs presents a table showing that practically no flagellates or ciliates are found at the surface of an Imhoff tank but the numbers increase with depth so that at 20 feet below the surface the former number 1200 and the latter 800 per c.c. In both influent and effluent the flagellates number about 75 per c.c. and the ciliates 20. The most abundant bacteria in the Imhoff tank are those that attack the most easily digested protein material, like bacteria, which attack soluble protein with the production of ammonia. A table dealing with this phase shows that there are more bacteria that are reducers of nitrogenous compounds than there are oxidizers of nitrogenous compounds.

Investigations of sprinkling filters shows that when there is a very heavy film on the stones that breaks up and passes through the filter, making purification unsatisfactory, considerable numbers of fungi are associated with the films. Nitration increased rapidly after the slough and when the film around the stones becomes thicker nitration decreases. (*Eng. News-Record*, May 3, 1923, 90, 18, p. 779).

Profit in Government Cafeteria

An article by Anice L. Whitney describes the health and welfare activities in the Government Printing Office. (*Month. Lab. Rev.*, May 1923, xvi, 5, p. 887).

The financing and management of the cafeteria are in the hands of a voluntary employees' association. The equipment of the lunch room and kitchen was purchased by the Printing Office. The kitchen is electrically equipped throughout. During the first year of operation the gross receipts amounted to about \$195,700. For the month of January, 1923, the

average receipts per meal were 19.8 cents and the average cost per meal 18.9 cents, leaving an average profit per meal of 0.9 cent. For February the profit was 0.7 cent per meal.

The hospital department has recently been extended from a single room to a suite of four rooms. The staff consists of two physicians and three nurses. All employees are given complete physical examinations upon entering the service. Since the inauguration of a detailed system of reporting, absenteeism in the plant has been greatly reduced.

Industrial Wastes in Relation to Water Supply

The injurious effects of industrial wastes on water supplies and water purification processes are becoming more and more important. The progress report of the Committee on Industrial Wastes in Relation to Water Supply (*J. Am. Water Works Assn.*, May 1923, x, 3, p. 415), prepared under the direction of Chairman Fales, is a valuable reference source for those interested in this problem. This report incorporates the more essential features of the preliminary report of 1922 together with more recent material. The valuable though incomplete information contained was derived from questionnaires sent to various public officials. The replies indicate that 248 water supplies, widely distributed throughout the United States and Canada, have been affected by industrial wastes.

The report considers among other things the pollution resulting from sugar refineries, coal mines, gas and by-product coke wastes, wood distillation wastes, corn product wastes, wastes from manufacture of dyes and intermediates, from the manufacture of munitions, leatherboard, and metal pickling and galvanizing plants. Wastes from oil wells and refineries, paper pulp mills, sawmills, tanneries, and textile mills add to the general list of offensive products.

Whether the solution of the problem shall be by (a) treatment of the polluted water, (b) treatment of industrial wastes prior to discharge, (c) or elimination of industrial wastes from the source of water supply depends on the local conditions. Due consideration must be had for established industries and unreasonable measures should not be used against them. "The problem must be considered from the broad viewpoint of public welfare."

NEWS FROM THE FIELD

Compulsory Labor Insurance in Japan

Japan is planning to establish a compulsory labor insurance system to provide relief for workers who suffer from injury or sickness. The plan being drafted by the Social Affairs Board will include all employees who receive twelve hundred yen or less per year and will allow 60 per cent of their wages during periods of disablement. Free medical attention will be an additional provision and, in case of death, funeral expenses will be paid. Three per cent of the costs will be deducted from the wages of the employee, and employers will pay the rest. Administrations costs of the fund will be borne by the treasury department.

Labor Census Being Taken in Japan

Japan has indicated her intention of taking every three years a census of labor. All factories employing thirty or more will be required to make a report to the government for the compilation of a report which will include the name and location of factories, kind of business, number of employees, working hours, holidays, and rest periods. Each employee is also required to fill out a card indicating name, age, sex, birthplace, education, wages received, allowance in kind, etc. It is expected that this census will assist the Government in enforcing the provisions of the factory law, which was recently amended.

Atmospheric Hazards in Railway Tunnels

Hot exhaust gases as the source of danger to locomotive crews exposed to atmospheres containing carbon monoxid or to atmospheres of high temperature and saturated with moisture are the subjects of Serial Report 2494 of the Bureau of Mines. On the basis of the tests made it is held that conditions in the caboose of locomotive engines might be severe enough to cause asphyxiation or exhaustion in periods of twenty minutes, especially in cases where the engine is stalled. Pocket respirator and other types of gas masks, packed with soda-lime charcoal mixtures af-

ford protection against smoky and sulphurous gases. Carbon monoxid masks afforded protection against all the gases encountered, but the most satisfactory method found for overcoming the tunnel atmospheres was by supplying air to members of the engine crew through respirators attached to the train air brake pipe line.

Czechoslovakia Drafts Bill Providing Old Age Pensions

The committee appointed by the Czechoslovak Parliament to draft the bill providing for an old age and invalid insurance has just completed its task, reports the Czechoslovak Consulate General in New York City. The proposed bill provides that the existing institutions for sick insurance will be amalgamated with the new state organization for old age and invalid insurance. Every manual and intellectual worker will automatically become a member of the new insurance corporation as long as he enjoys steady employment. In dispensing benefits the state will construe the word "invalid" as applying to an incapacitated person who is no longer able to earn two-thirds of a specified living wage. The report continues:

"The old-age pension will be granted to all insured citizens who have reached the age of 65. Widows will also receive their proverbial mite under the Insurance act on becoming invalided, or on attainment of the prescribed age, and orphans will be provided for under this bill until their seventeenth year. Every one participating in the insurance scheme—and there will automatically be 3,250,000 persons paying and receiving insurance money from the outset—will contribute an average premium amounting to 6 per cent of his total wages or salary. And each beneficiary will receive a fixed annual payment, the same in every instance, which will be augmented by a State supplement. The burden of the insurance payments will be borne equally by the employer and employee; each employer will be compelled to meet one-half of the laborer's insurance obligations."

Missouri's Trachoma Hospital, Rolla, Mo., was formally opened July 24. The institution was established and conducted under the joint auspices of the state board of health and the United States Public Health Service.

Women's Prison Association Makes Report

Women prisoners, states Mrs. Margaret B. Steinmetz, general secretary of the Women's Prison Association, are so few and far between that it is difficult to collect the necessary data in regard to prison conditions affecting them. On days she was making her tour of inspection at one time she found no woman in twenty-seven jails visited. In fifteen jails she was told that no woman prisoner had been received during the year.

The old-time type of alcoholic men and women do not go into the county jails now, she says, but are found in hospitals or asylums, or have had suspended sentences. In the increasing number of drug addicts there is a more criminal class of young men and women, she was told, and these drug addicts are a perplexing problem.

The woman cigarette smoker is found inside as well as outside the jail, and where they find it a great hardship to do without smoking, they are allowed to purchase cigarettes. A number of bright women were found at Auburn Prison serving long sentences, and one of these was taking a correspondence course at Columbia University.

Old-Age Pensions in America

Three states—Pennsylvania, Montana, and Nevada—have enacted old-age pension legislation this year. Each of these states allows persons seventy years of age or more and having no incomes, or incomes not exceeding three hundred dollars a year, pensions of twenty-five dollars a month, minus the amount of their incomes.

Legislation in this regard is based upon the results of inquiries in several states which reveal a surprisingly large number of aged persons dependent upon organized charity and upon the premise that the payment of pensions is economical and in every way preferable to the maintenance of poor houses and county relief. Wherever a study has been made, present provision either by industry, insurance funds, or public measures has been held inadequate.

The Federation for Child Study Summer Play Schools is making it a part of its educational program to train the children of the play schools not to throw litter anywhere in the parks except in the cans provided for them, and to work everywhere for a cleaner city.

Twelve-Hour Day Disappears in American Industry

The immediate effect of the abolition of the twelve hour day in the steel industry, which is just becoming effective in the United States is hailed by the press as a health measure primarily, cannot fail to be favorable to the workers. That it need not hurt industry is proved by the quantitative report on output in the porcelain ware industry just put out by Association of Porcelain and Allied Workers of Germany, and commented on by the *New York Times*.

Comparison was made between the output of a number of plants in 1914 under the ten-hour day and in 1922 under the eight-hour regime, and the relative increases in production for worker ranged from 12 to 119 per cent.

For instance, the average turner of salad dishes in 1914 completed 1,000 pieces in fifty-eight hours, while in 1922 he turned out 1,500 in forty-eight hours; plate makers increased their average output from 2,200 to 3,500, and cup turners completed 5,500 pieces a week in 1922, against 3,000 in 1914. About the same average increase in production held good in the painting division of the industry, as was also the case in the auxiliary establishments connected with porcelain factories. Even in plants where only high-class wares were manufactured the increase in out-put ranged from 12 to 32 per cent.

A writer in the Berlin *Vorwärts* explains that the porcelain ware makers are on piece work and have to do their utmost in order to earn enough to keep alive, and he warns them against speeding up to such a degree as to counteract the benefits obtained by the shorter work day.

Brochure on Biologic Products and Public Health

The *Commonhealth*, distributed free by the Board of Health of Massachusetts, has brought out a biologic number summarizing existing practical knowledge concerning the theory and application of biologic products with special emphasis upon those products manufactured and distributed gratuitously by the state. Useful commercial products are also described with reasons why they are not so made and distributed. The paper of Eugene M. Kelley, M.D., commissioner of health, and Benjamin White, Ph.D., director, Division of Laboratories, is particularly valuable as it appends a complete table of the diseases in which biologic products for diagnosis treatment, or prevention are available. The issue is a valuable reference book on the place of vaccines and vaccine therapy in state health.

Transaction of Cremation Society

The Transactions of the Cremation Society of England No. 34 presents the proceedings of the conference of the society in October, 1922. The questions discussed are the substitution of cremation for burial, the best means of spreading information on the subject, and the doctor's fee for the medical certificate. "The dead are very much more numerous than the living," to quote Dr. Chalmers Mitchell at this conference, "and every year they are getting more and more numerous, and the living cannot afford the present arrangements."

During 1922 the number of cremations which took place in Great Britain were 2,009, or 87 more than in 1921, but in the provinces there was a decrease.

Child Health Scholarship Fund

The American Child Health Association is advertising a ten thousand dollar fund to be devoted to resident and travel scholarships for physicians who want to improve their qualifications for child health work. Freedom of choice of institutions is allowed among those offering approved courses, the work to be undertaken during the school year 1923-1924 and the summer of 1924. Application is to be made to the American Child Health Association, 370 Seventh Avenue, New York City.

Program of Council of Jewish Women

The sub-committee on public health, of the Council of Jewish Women, headed by Dr. Luba Robin Goldsmith, offers material for health propaganda and exhibit material including lectures, the organization and direction of study circles, courses in first aid, and training as aides in health work. The practical work is obtained through health stations, and intelligent support in health campaigns for the prevention of disease is advocated.

Michigan Rural Health Campaign

A "health evangelist" is being sent out by the Michigan Tuberculosis Association to preach anywhere he can find an audience the gospel of health. He is furnished with a specially built automobile with a moving picture machine and stereopticon slides on health topics, a complete out-door living equipment and his special objective is preliminary organization for work in rural education along health lines.

Sickness Costs in Detroit

An investigation conducted by the social service department of the Detroit Department of Health into the average economic loss of patients served by the venereal clinic revealed a total loss of 24,152 days of work for one thousand patients, or \$183.83 per patient. The loss for the group studied, including wages lost, cash paid out for treatment, costs for future treatment, and continued unemployment made a total of \$168,590.

The average yearly attendance at the department of health clinic is approximately ten thousand new positive patients annually. The cost of physical unfitness due to venereal disease is estimated on this basis to be \$1,685,900 per year.

International Union Meets in Paris

The annual meeting of the International Union against Tuberculosis was held in Paris July 26, 1923, at the headquarters of the League of Red Cross Societies. Twenty members met under the presidency of Dr. Devez of Brussels.

Professor Léon Bernard, Secretary General, gave an account of the development of the Union since the Brussels conference. It was decided that the following questions should be placed on the agenda of the conference to be held at Lausanne in September, 1924:

(1) Relations between pregnancy and tuberculosis, to be reported on by Professor Forsner (Stockholm);

(2) Do there exist naturally or can there be produced artificially saprophytic forms of Koch's bacillus which might become virulent tuberculosis bacilli? Report by Professor Calmette (Paris);

(3) Effects of the organization of the anti-tuberculosis campaign in different countries on the decrease in tuberculosis mortality. Report by Sir Robert Philip (Edinburgh).

St. Louis Infant Mortality

The city of St. Louis complains to the *New York Times* that, on account of the fact that Missouri has not been admitted by the Government to the Registration Area, St. Louis has suffered some invidious comparison with other cities in the matter of infant mortality rates based on reports of the American Child Health Association. A report from Paul V. Bunn, General Secretary of the St. Louis Chamber of Commerce gives the death rate of 61.7 per 1,000 for 1921 and less than 57 for 1922.

Ten Million Pensioners from World War

The number of persons who are drawing pensions because of casualties in the World War from the several countries is reported by the International Labor Bureau to be around ten million. Distribution is as follows:

Germany has 1,537,000 pensioned men, Australia 76,000, Austria 164,000, Belgium 50,000, Canada 45,000, the United States 157,000, Finland 10,000, France 1,500,000, Great Britain, 1,170,000, Italy 800,000, Poland 320,000, Rumania 100,000, Yugoslavia 164,000, Russia 775,000, Czechoslovakia 236,000 and New Zealand 20,000.

Statistics are lacking for Turkey, Bulgaria, the Baltic States, Portugal, Hungary and Japan.

Child Labor in Japanese Factories

A survey of labor conditions in the cotton mills of Japan is reported in *The American Child* from which it appears that four-fifths of the workers employed in Japanese spinning mills are women and girls, and of these nearly two-thirds are under the age of twenty. Out of 177,476 women and girls employed in 1919, seventy-nine were under twelve years; 32,722 were between twelve and fifteen years; 79,656 between fifteen and twenty years; and 65,016 over twenty years. The number of men and boys employed was 55,330, almost all over fifteen years of age.

The factory act, which sets the minimum working age at fourteen, allows children of twelve to work when they have finished the course of an elementary school, or if they are in employment when the act comes in force. The new act stipulates that children under sixteen, and women are not to be employed more than eleven hours a day, which is one hour less than is allowed at present.

Baltimore to Compensate Aged Employees

Baltimore, Md., has under consideration an ordinance to create a department of compensation and pensions "to provide for the pensioning of certain aged or disabled employees of the city of Baltimore to provide medical attention and compensation for certain employees of the city injured in the course of their employment, and to provide compensation for the dependents of certain employees dying as a result of injuries

sustained in the course of their employment."

Smallpox Inimical to English Trade

Dr. Wanklyn of the London County Council Health Department is quoted by the *London Times* as saying that five hundred thousand cases of smallpox are not uncommonly reported from British India in a single year. Trade convergence in Great Britain renders Englishmen especially liable to infection. Last year upwards of nine hundred cases occurred in England and more than a thousand cases of smallpox have been noted in England the present year.

In the circumstances the present neglect of vaccination is little short of tragic, Dr. Wanklyn declares, as only about 38 per cent of babies born today are protected by that means. Present conditions carry warnings it is the utmost of foolhardiness to overlook, as increasing virulence as well as increasing incidence point to a far greater need for vaccination than has existed for some time past, and pressure in favor of this measure can well come from the business world.

Physical Examination of Children Entering Industry

In twenty-two states a physical examination is required of every child applying for an employment certificate and one state—Virginia—requires periodical examinations of working children to determine whether the work at which he is engaged is proving injurious to his health or interfering in any way with his development.

Eighteen states still have no legal provision for examinations of any kind, even when a child first enters employment.

The July *Statistical Bulletin* of the Metropolitan Life Insurance Company reports the following tendencies for the first half of 1923 in the mortality records of its policy holders: Tuberculosis mortality still declining; fewer deaths from cancer; lower rates from cancer; lower rates from cerebral hemorrhage; lower mortality among whites from organic heart disease; a general drop in death rate for puerperal diseases; comparatively low rate from pneumonia; lower diphtheria mortality; higher rates for measles and whooping cough. Fatal accidents are reported as more numerous in 1922 than in 1921, and mortality from alcoholism, paradoxically, is rising in the United States, and falling in Canada.

Test Music as Medicine in Hospital

As a result of a sixty day test, good music will now form a part of the treatment in the New York Nursery and Child's Hospital. In speaking of the results Dr. Harold C. Cox, the resident physician said:

"The test was tried mainly with the mothers in the maternity wards, but also with the babies and sick children. Whether it was the appeal of rhythm, we do not know, but the tests have amply demonstrated that music has a marked therapeutic effect on the spirits and general morals of hospital patients. Incidentally, the music is highly popular with the nurses."

Twenty-five extra health officers have been appointed in New York to cover the city in inspection of wagons, push carts, etc., used in selling candy, ice cream and various kinds of drinks on the streets. Investigation has shown that children form the greatest numbers of customers for these street vendors and that many of them are handled in a most insanitary manner. Especially in the selling of drinks, almost none of the wagons have any facilities for cleaning the glasses and in no case has it been found that the equipment was sufficient to make the glasses clean.

Parole System Being Tried Out for Lepers in Honolulu

A parole system has been in use at the Kalihi Hospital near Honolulu with a great measure of success. In all 242 lepers were paroled, thirty-one relapsed and ten were completely relieved from parole.

Those paroled, by carrying good reports of the treatment accorded them at the hospital have done much toward combating the prejudice, and by the mere fact of their release show that segregation may lead to a cure.

As a result of this system many who have been concealing this disease have come forward voluntarily and asked for treatment. About 70 per cent of those paroled had been segregated for less than two years.

Delegates to the International Congress of Surgeons held in London July 18, were told that the British rate in recent years has been reduced from 17 per thousand to less than 13 per thousand, and infant mortality from 133 per thousand to 77 per thousand.

HEALTH PUBLICATIONS REVIEWED

The Pre-School Child

The increasing emphasis upon the problems of the pre-school child both from public health and educational angles has opened up many possibilities. The present volume, "The Pre-School Child from the Standpoint of Public Hygiene and Education" by Arnold Gesell is an attempt to survey and interpret the problems of the pre-school child from the point of view of public hygiene and education. In this he includes material of great interest to those employed in related work, such as a summary of agencies dealing with the pre-school child, the nursery, the kindergarten, the handicapped child and other related subjects. In dealing with the problems of social control and the administrative organization of pre-school hygiene, he has stressed the significance of pre-parental education particularly.

Houghton Mifflin, Boston, 1923.

The Tuberculosis Worker

The author Philip P. Jacobs, in "The Tuberculosis Worker," has attempted to bring together knowledge of the experience and technique underlying the development of tuberculosis work during the last twenty years. He deals with two things; methods and programs of tuberculosis work. The book is based upon the activities of the many organizations dealing with the problems and is one which should be thoroughly studied by every health or welfare worker. The use of exhibits, the motion picture, the clinic, the nurse, the open air school and the many other methods are all carefully analyzed and evaluated.

Williams and Wilkins Company, Baltimore, 1923.

The Health of the Runabout Child

A popular but very sound discussion of the infant and child in "The Health of the Runabout Child," by William Palmer Lucas, offers food for thought to all interested in "the art of parenthood in this century of the child". As the author points out we now recognize certain children's rights: the right to be well-born; the right to the personal care of both

father and mother; the right to be fed, clothed and cared for physically; and "the right to learn from parents by example and precept the principles of truth, honor, purity and right living."

This fourth right, it is said, emphasizes the change in the historical attitude of parent and child. It is no longer a relationship of ownership but of trusteeship. "Not what a man and woman can get out of their children, but what they can put into their children, that is the test of parenthood." Dr. Lucas presents very readable material about normal growth and development, hygiene and health problems, common diseases, defects, foods, play, happiness, and habit formation in such a way as to be of wide general interest and use.

The Macmillan Company, New York, 1923.

Graded Outlines in Hygiene

The importance of adequate instruction and training of school children in the fundamentals of hygiene have been increasingly emphasized but unfortunately there is the greatest variation in the methods of presenting the subject matter and the actual content of the same. "Graded Outlines in Hygiene", by Walter Frank Cobb, develops certain dosages which can probably be administered by the average teacher without injury to herself or her pupils. The incidents, lessons, pictures and stories are all intimately related to the child's ordinary experiences; the organizing of material, the daily program, personal habits, physical education are all considered. Many valuable suggestions and anecdotes are related to demonstrate the methods of effectively presenting the subject.

World Book Co., New York, 1923.

The Black Candle

The author of "The Black Candle", Emily F. Murphy, as police magistrate and judge of the Juvenile Court at Edmonton, Alberta, has had the opportunity to observe the steadily increasing illicit traffic in narcotic drugs in Canada and the United States. She has studied the problems involved carefully and here presents a very thought provoking book. Statistical material in general is apt to

vary, but, the material gathered from official surveys and reports carries a weight of opinion not to be disregarded. Thus of 3,000 drug addicts treated at the New York State Clinic, 908 were between fifteen and nineteen years of age; 927, between twenty and twenty-five; 711, from twenty-six to thirty; 523, from thirty-one to forty; 133, from forty-one years or older. It was found that 429 attributed their addiction to illness; 351 to curiosity, pleasure or trouble and 2,482 from association with traffickers. A Canadian peddler boasted that he had been in the Dominion thirty years, during which time he taught two thousand people how to smoke opium. The drug habit is to be considered as a disease and provision should be made for its treatment under governmental protection. The police cannot alone control the situation. The author suggests a government monopoly of drugs, no profits chargeable.

George Allen and Company, Toronto, 1922

Moonlight Schools

Adult illiteracy and education is a problem considered more or less optimistically by many. We are appalled by its extent, but consistent reasonable measures to combat the situation have not been so widely developed as might be hoped. Moonlight Schools were first established September, 1911, in Rowan County, Kentucky, to combat the extensive illiteracy and to afford those of limited education, who so desired, to improve their knowledge. The movement has grown and spread as the problem has been defined and as resources have been available. The present book "Moonlight Schools", by Cora Wilson Stewart, is a very interesting narrative of some of their difficulties and accomplishments.

E. P. Dutton & Co., New York, 1922.

The Employees Compensation Commission

The Employees' Compensation Commission, its history, activities, and organization have been the subject of recent study by the Institute for Government Research, the report of which has been brought out as one of a series of service monographs (No.

12). The history and development of the service, its organization, the character, its activities, a compilation of the laws and regulations governing its operations, and a financial statement of its appropriations and expenditures are shown over a number of years. The monograph is complete in its bibliography and constitutes the most comprehensive statement of the subject that is available.

D. Appleton & Co., New York, 1922.

P. H. Nursing in Philippines

A pamphlet recently issued by the Philippine Health Service describes an important step taken in the establishment of a course in public health nursing arranged by the Service in cooperation with the University of the Philippines, the Philippine General Hospital, the Bureau of Public Welfare, the Red Cross and certain charitable and philanthropic organizations in Manila. The first six months course began August 1, 1922, with theoretical instruction in public health nursing, preventive medicine, vital statistics, sociology and charities and home economics. Practical field work was provided in connection with the Philippine Health Service, the Public Welfare Commission, the Philippine Chapter of the American Red Cross, the San Lazaro Hospital, the Department of School Inspection, the Anti-Tuberculosis Society and the milk stations with special visits and excursions to other points of sanitary interest. Thirty graduates completed this first course. Seventeen of them accepted positions with the Red Cross, eight with the Philippine Health Service, three with the Public Welfare Commission and two with the Anti-Tuberculosis Society. A second course opened May 15, 1923.

Increasing Virulence of Smallpox

During 1922, the case-fatality rate of smallpox, or the number of deaths per one hundred cases, was five times the figure for 1921! Among 9,936 cases reported in 276 cities in the United States and Canada, 495 deaths occurred, or 5 per cent of the total cases. In 1921, only 1 per cent of the 31,489 cases died. The decline in the number of cases may be only a casual circumstance; the lesson to be drawn from the records of the year is that smallpox in a virulent death-dealing form has entrenched itself in recent years among the American and Canadian populations. No one can now tell when, where, or to what

extent this killing form of the disease will next make its appearance. The wide acceptance of the false teachings of the anti-vaccinationists and the indifference of the American population to the continued and vehement warnings of its public health officials have prepared tinder for what may well become a catastrophe of the first order. At last, we can see very clearly where the two national sins of tolerance of scientific error and of drift are leading us, says the April issue of the *Statistical Bulletin* of the Metropolitan Life Insurance Company.

Interstate and intercity transportation afford ready means for the spread of virulent smallpox infection from the Western areas, where it has recently prevailed, to all other parts of the North American continent. In Kansas City, Mo., the type of the prevailing disease resulted in death in 46 per cent of the cases; in Kansas City, Kan., in 42 per cent; in Denver, Colo., in 31 per cent and in Moberly, Missouri, in 39 per cent of the cases. Chicago showed a case-fatality rate of 16 per cent; Tucson, Ariz., 20 per cent; Muskegon, Mich., 38 per cent, and Okmulgee, Okla., a rate of 85 per cent.

The Habit of Health: How to Gain and Keep It

This book "The Habit of Health" by Oliver Huckel seems to have grown out of a series of conferences at the Johns Hopkins Medical School some years ago having for their purpose the closer cooperation of physicians and ministers. The author led these discussions and is here publishing in a briefer form some of the suggestions there made, what he terms, "a broad-gauge plan for the unity of mind and body" which include spirituality, faith, recreation and work among other things.

Crowell Publishing Company, New York, 1922.

Loss of Life Not Due to Disease Alone

Disease is no longer the single important factor in the loss of human lives, says the Michigan Department of Health. In Michigan automobiles have been the chief offenders for the first six months of 1923, claiming 204 victims, exclusive of grade crossing accidents, as against 180 for the same period of 1922. Accidental drowning has likewise increased in Michigan for this year, the 1923 figure being 120, and the 1922 toll 104 for the same period.

Correction

In the "Health Publications Reviewed," section of the September issue of THE NATION'S HEALTH the address of the publisher of Krause's two books on Tuberculosis was given as New York City. This firm, William & Wilkins Company is located at Baltimore, Md.

The Pennsylvania Medical Journal and the Delaware State Medical Journal have combined to form a larger and better publication under the name of *The Atlantic Medical Journal*.

Public Health Development in Siam

(Continued from Page 677)

(2) Health administration. This includes infant welfare work and direct and cooperative health educational work with the Health Section of the Siamese Red Cross Society.

(3) Control of epidemic diseases.

(4) Public Health Inspection. This includes public health laboratory service.

(5) Inspection of medical services, including care of the insane.

Work of Municipalities

In addition to its direct health activities, the National Department of Public Health exercises advisory control over the health activities which, not being national in their scope, are conducted by municipalities such as the city of Bangkok and the smaller cities. The law¹ for the organization of these local boards of health defines their purposes as follows:

The purposes of these local boards are: The maintenance of cleanliness; prevention and treatment of disease; maintenance and construction of roads; record of births, deaths, and other vital statistics; the carrying out of vaccination; the development of means for the collection and disposal of refuse and filth; the protection of domestic water supplies.

Such local boards of health have now been organized in twenty-five interior towns. Seven of them maintain small hospitals, and fifteen maintain dispensaries.

The health work of the city of Bangkok is conducted under a separate budget through the office of a medical officer of health. The program of the office includes (1) hospital administration, (2) laboratory service, (3) maritime quarantine for the port of Bangkok, (4) infectious disease control, (5) sanitary inspection, (6) provision of public abattoirs, (7) medical service for the Bangkok prisons.

Red Cross Cooperates

Health work in Siam is being greatly aided by the Siamese Red Cross Society, which operates through the following sections:

(1) Hospital Section, which maintains the splendidly equipped Chulalongkorn Hospital.

(2) Scientific Section, which maintains the Pasteur Institute, one of the finest institutions of its kind to be found anywhere. It prepares all of the anti-smallpox vaccines used in

Siam, the material for anti-rabic treatment, and sera and vaccines of all kinds, as required.

(3) The Health Section, which in cooperation with the International Health Board, is conducting a vigorous work along the following lines: (a) Hookworm control campaigns; (b) Hookworm survey and health propaganda campaigns; (c) Public health education; (d) Anti-leprosy work; (e) Public health nursing (now being organized).

(4) Relief Section, a skeleton organization for emergency service.

Old method of disposing of night soil.

(5) Junior Red Cross (in process of organization).

Organized Health Work

It may be of interest to point out some of the important achievements of organized health work in Siam.

Health Education

The Department of Public Health has conducted a considerable amount of health educational work. The medical officers of health (Dr. R. W. Mendelson) has published a long series of health articles in the Bangkok newspapers and has posted all over the city of Bangkok large signboards calling attention to the means of preventing cholera, smallpox, and plague. The Ministry of Education gives a certain amount of instruction on hygiene in the schools and in the Boy Scout or-

ganization. The health section of the Siamese Red Cross Society has been a most effective agency in conducting educational work. In this it has been largely assisted by the International Health Board. The latter organization has also cooperated with the Department of Public Health in an effective series of hookworm campaigns, and its units, in making their surveys, have carried to every part of the Kingdom a strong health propaganda. Nothing has ever so stirred the public in the matter of sanitary reform as have these campaigns, and the beneficial results are already beginning to appear over a wide area.

Health education through exhibitions is being effectively employed. During the past year two large exhibitions organized cooperatively by the Siamese Red Cross Society and the Department of Public Health have been held. One of these, maintained in Bangkok for fifteen days during November and December, 1922, was attended by 220,746 persons.

Up to the present time, only two cities in Siam have been provided with municipal pure water supply, namely, Nakorn Patom, and Bangkok. The former has an artesian supply. The latter has one of the most modern types of purifying plant. By daily bacteriological examinations, a constant control over the efficiency of the treatment of the water is exercised. Cholera has largely disappeared from the sections of the city that are supplied from this source.

Epidemic Diseases

Due to the increasing mobility of the organized health forces and the improved means of transportation, the outbreaks of cholera which occasionally appear are dealt with more promptly, and do not now become so extensive as in former years.

Work against plague is carried on under the greatest difficulties. However, when an outbreak has become severe enough to persuade the officials to give the Department of Public Health a free hand, some very effective control work has been done. As an instance, the outbreak in the city of Korat (population 6,000) may be cited. For a number of years plague was endemic in that city, but in 1917 it took on an epidemic form, carrying away 10 per cent of the population before it was brought under con-

¹ Report of the Department of Public Health, 1922, p. 112.

trol. When the department was given full freedom of action, it conducted such prompt and efficient work that not only was the epidemic speedily controlled, but no cases of plague occurred in that city for the next four years.

During the past nine years a total of 3,418,444 persons have been vaccinated against smallpox. Of these 460,195 were vaccinated in the year ending March 31, 1922. This is a good record when one considers the difficulty of transporting and keeping active the vaccinal lymph in a tropical country. Formerly, it required several weeks travel to reach the distant provinces. Now, however, in emergency, vaccines² can be sent to such places by aeroplane. "For preserving the vaccine during transportation, thermos flasks have been tried but without brilliant results. The present routine method is to pack the tubes in wet sawdust in sections of bamboo. These are then frozen (-10° C.) and removed from the refrigerator immediately before shipment. In the actual presence of smallpox, the vaccine is shipped encased in blocks of ice when practicable."

Public Health Laboratories

The Pasteur Institute maintained by the Siamese Red Cross Society prepares not only antirabic treatments, but also all of the smallpox vaccine used in the Kingdom. In addition it prepares antivenene, curative sera of various kinds, plague vaccine, and so forth. It also is doing an increasing amount of public health laboratory work. The laboratory of the Local Sanitary Department (Bangkok) does the daily water analyses of the city water supply, examines rats for plague, and dogs for rabies, and does a large amount of other public health laboratory work. The government laboratory of the Ministry of Commerce, in addition to the routine analyses for the mint and the customs department, does medico-legal work and the preparation of such other supplies as the ethyl esters of chaulmoogra oil.

Hospitals and dispensaries have been established under various agencies in the important towns of the Kingdom. These are of varying degrees of efficiency, but they represent a distinct advance, especially when one remembers the limited number of well-trained physicians in Siam.

The Future

In conclusion, it may be pointed out

². Report of the Department of Public Health, 1922, p. 80.

that the conditions for health work are becoming increasingly favorable. The subject has been given a great deal of publicity during the past few years and this is having its effect. The newspapers are beginning to take up the cudgels, and in addition to the liberal amount of space given to health articles, letters from "Pro Bono Publico" and other serious-minded gentlemen frequently appear attacking notorious nuisances. The Siam Medical Association has been organized, comprising some three hundred of the physicians trained in Siam. This organization is beginning to agitate against certain existing evils. Siamese physicians have recently been sent abroad under various auspices to study public health and on their return their work along that line should be a great asset to the various health organizations.

If, under the adverse conditions of the past, the work outlined above has been possible, we may look for a much more satisfactory advance in the coming years.

Chemical Energy to Restore Fatigued Muscles

During the war we heard all sorts of wild rumors about the German soldiers being given some sort of chemical that endowed them with supernormal energy as they charged the enemy or endured forced marches. Doubtless various things were tried, including that old and unreliable stimulant, alcohol, and the newer and less exciting energizer, sugar.

But it has now been disclosed, says the current issue of *The Scientific Monthly*, that the most remarkable results in the endurance were obtained from the use of a well known salt, called by the chemist "sodium dihydrogen phosphate." This was given to the shock troops as they entered battle or during long marches in the form of a drink. To avoid the influence of psychological suggestion, which has invalidated so many tests with "poison squads" and experimental subjects, other battalions were served with a sham drink sweetened and flavored the same, but acidulated with tartaric instead of phosphoric acid. At the end of a hard, hot day the troops that had been treated with the phosphate were fresher in spirit and less fatigued in body than the others for some reason mysterious to them.

Since the war it has been found that giving phosphate drink to coal miners and farm laborers, increased their monthly output without extra exer-

tion. Horses and oxen given an ounce of the salt a day did more work and gained flesh. Here there could be no deception due to the imagination.

This practical and promising method of increasing human and animal efficiency came from the investigations of one of the foremost of German physiologists, Professor Gustaf Embden, of Frankfurt University, on the chemistry of nutrition. According to this theory muscular energy comes from the breaking down of a substance called "lactacidogen," which he regards as a compound of sugar and phosphoric acid. This breaks down, when the muscle contracts, into lactic acid and phosphoric acid. Lactic acid, as it has long been known, accumulates in a fatigued muscle and has to be recombined or oxidized before the muscle can work again. So Embden reasoned that adding phosphoric to the diet would hasten the combination of the phosphoric acid with more sugar and so relieve the fatigue. The war gave him the chance to experiment on whole regiments at a time and the results seem to confirm his theory.

The new stimulant has the advantage over alcohol or the alkaloids in that it is a natural factor in bodily process, and also in that there is no danger of intoxication from an overdose or of forming a habit. Doses up to a quarter of an ounce a day were given to the soldiers and laborers. More than this, and sometimes much less than this, has a laxative effect.

The report of these experiments is likely to multiply calls for phosphate drinks at the soda fountains, but the anticipated increase of muscular vigor may fail to be felt, for when the man behind the marble counter mixes a phosphate he throws in a dash of a very dilute solution of phosphoric acid, and a person would have to take some fifty such drinks to get the amount used by the soldiers.

Less than 5 per cent of lepers in the British Empire are being cared for in any way, according to a statement from a group of physicians who have organized themselves into the British Empire Leprosy Association, and only a small proportion of these are receiving the recently improved methods of treatment. The Association has as its objective the eradication of leprosy within the empire, an undertaking to be initiated by a general committee including leading physicians, authorities on tropical medicine, and public men.

United States Government and the Disabled

(Continued from page 679)

of the patient to be treated. With such care in its use the ultraviolet rays may be absorbed into the blood to improve the quality of the blood chemistry and the blood cells.

In another room of this unit are the latest type of static machines with various currents of extremely high voltage and infinitely small amperage. War hospital experience proved that these pulsatory static currents are of value in a surprisingly wide range of affections, being particularly useful in the treatment of injuries and diseases that are not due to germs.

The high quality of treatment for our invalid veterans depends alike on the physicians in charge who are specialists in physiotherapy as on the highly trained technicians who actually give the various applications, and who are officially known as "aides." These aides are, for the most part, graduates of the various women's colleges of the country and, in addition, they have been especially trained in physiotherapy so that they achieve the maximum results. In this clinic, alone, there was given 8,384 treatments during the month of January, 1921.

In another section of the dispensary is the dental clinic and it is no exaggeration to say that it is the finest example of its kind in the country. Its equipment includes twelve operating chairs, one chair for oral surgery, one chair for examinations, one x-ray chair and machine, and an up-to-date dental laboratory with two chairs for impressions. With a personnel including one chief of clinic, one assistant, twelve operators, two oral hygienists, one x-ray technician, four mechanical dentists, one nurse, six dental assistants and, in the laboratory, four disabled ex-

service men being trained in mechanical dentistry, there are treated, on an average, one hundred thirty-five men a day. Another section of the clinic of which the Veterans' Bureau is justly proud is that of the x-ray.

body: have these located immediately and actually visualized in situ. Radiographs are always taken and kept in file so that at any future time reference can be made to them for comparison or as otherwise needed.

Studies may be made of the chest, the actual movements of the heart, or the lungs during respiration. In examination of the stomach by means of an opaque substance the food can be seen passing from the esophagus to the stomach and any abnormalities or stigmata of disease can be visualized and then recorded on a film for permanent record. The developing is done immediately so that bone lesions, etc., can be demonstrated and reported in a few minutes, if necessary.

A separate dental exposure room is opened independently of the main exposure room which is an added asset to the busy dental clinic.

A fully outfitted workshop is an essential of the orthopedic clinic, and here are made all the artificial limbs, etc., needed for the crippled veterans throughout the entire district. Fitted with a full outfit of machinery for this purpose, these orthopedic demands are supplied by three departments—the mold room, the shoe room and an artificial limb repair and leather room. In the mold department a plaster cast mold of the disabled man's deformity is made, and from this mold all braces, shoes, etc., are constructed that are built in the clinic. All the shoemaking in this section is done by hand and is a very high type of work. Artificial limbs and braces of all types

are also made in the orthopedic section at a great saving to the government. It was estimated that the average cost of a pair of orthopedic shoes made in this section was twelve dol-

Diathermia (deep electrical heat penetration) followed by massage, exercises, and manipulations.

Here are to be found spacious rooms, well lighted, and adequately equipped with the very best and most proficient apparatus to be had.

Exposure rooms have every possible protection to patient and operator alike in the way of leaded walls,

General hydrotherapy. Application of Scotch douche concentrated on lower back.

insulated wires, etc.

The soldier carrying the maladies of Flanders' Field may come to the Clinic, say, with foreign bodies, shrapnel, etc., in any part of the

lars whereas, if they had to be purchased from some outside manufacturer their cost would average from three to four times as much. In this unit are four ex-service men, trainees of the Bureau, three of whom have each lost a limb. The fourth has charge of all the molding that is done.

One of the most interesting units of the dispensary is that of its scientific laboratory. Here all kinds of clinical, pathological, serological demands called for in dispensary treatment are satisfied. Presided over by an expert, experienced analytical chemist, the work of its high type personnel is evident in the extensive research studies and practical supplies constantly developed here.

Like the brook one could run on forever describing the various other features of this institution—for an institution this organization of 1,500 personnel has developed—but it is enough to say that they maintain the high standards of the ones already described. The general medical, surgical, eye, ear, nose and throat, and neuro-psychiatric units, under the control of high grade experienced physicians, surgeons and psychiatrists, in turn are all that could be desired to furnish the best of modern medical science for our deserving war invalids, and these men are earnest, hardworking practitioners who have sacrificed all thoughts of personal gain to attend to a duty that, in their view, is the most humanitarian that offers at the present time. Careful, thorough, painstaking individuals, they are all schooled in the knowledge that the care of a disabled veteran is of paramount importance, (and who will say it is not), and that the place that this veteran assumes in the life of the community after his cure has been affected is, in a great many ways, up to them.

To make clear the magnitude of the work that is being carried on in this dispensary, the records for January, 1923, show us that 18,613 treatments were given in this clinic and that 579 outside calls were made. Such figures speak eloquently for the value of this service in its particular field of activity.

Another end of the dispensary program that is entitled to a great deal of praise is the consulting service. Here is a service open to all patients

of the Veterans' Bureau, that has enlisted among its numbers the greatest names found in the medical profession in this country, and it is brought up to such a fine point that the average cost of such treatments or diagnosis that are given by these consultants, exclusive of outside calls, costs the

General Tonic ultraviolet ray irradiation with best types of lamps for the production of artificial sunshine.

government twenty-six cents a man. It was established that should the ex-service men who received this aid call, as private individuals, at the offices of the men who treated them in the dispensary, the cost of the same treatment that they received would be from fifty to one hundred times as much. It has also been estimated that the entire clinic operates at an annual saving to the government of \$388,000 compared to costs for similar service in contract hospitals.

It is a task for a pen far greater than the writer's to paint, in all its colors, the vivid and graphic picture of the New York City clinic of the United States Veterans' Bureau. It would require the descriptive faculties of a master to present the work that is being done; its magnitude, its quality, and its results. Therefore, it is with a silent prayer that this is given to the reader; a prayer that in some small way he may see a part of the machinery that is carrying on the greatest rehabilitation program that man ever devised.

Illinois Nurses' Institute

CULTURAL background and breadth of social viewpoint rather than training in technic are the objectives of the League of Nursing Education, but both were successfully incorporated in the program arranged for the Illinois Institute for Nurses held in Chicago September 3 to 14. Fifty nurses attended a series of thirty lectures on psychology, sociology, and the principles of teaching.

The lectures on psychology by Professor Harrison LeRoy Harley dealt with the fusion of personality factors that account for characteristic reactions in individuals, with nature and character of the various dispositions in man, and with modifications through socializing influences. The topics included a demonstration of the application of mental tests and an exposition of the principles of psychiatric nursing.

William E. Blatz, instructor in psychology, University of Chicago, supplemented this course by ten lectures on the principles of teaching and emphasized the educational functions of the public health nurse. Technical aspects of the subject were treated under such subjects as the learning process, habit formation, how to study, and the art of questioning. The subject was rounded out in its sociological bearings by Thomas D.

Elliot, of Northwestern University, who made of his ten lectures a sort of social survey course, indicating broadly the concrete social problems involved in case work.

During the period of the Institute demonstration clinics were held in the various hospitals of the city illustrating technic in such subjects as: (1) The unit system in the management of contagious diseases; (2) the treatment of diabetes; (3) visiting nurse work for crippled children; (4) infant clinics; (5) physiotherapy; and (6) the conduct of surgical clinics. The closing day was given over to a visit to the Illinois State School of Psychiatric Nursing and the last session, held in Amusement Hall, Chicago State Hospital, was a play staged by nurses from the Visiting Nurse Association of Chicago which in scenes and incidents represented faithfully a page from their day's work.

Insulin, the widely heralded treatment for diabetes, is to be used in hospitals caring for war veterans. The medical director of the U. S. Veteran's Bureau has issued directions that a competent man must be designated in each hospital to qualify for handling diabetes, and to keep in touch with current progress.

The Training of Health Workers

(Continued from page 681)

from the reorganization of the Department in 1914, is the establishment by the Public Health Council of educational qualifications for public health nurses and the greatly extended utilization of these invaluable workers in routine public health activities. In many instances municipal departments and private organizations have employed as public health nurses women who have had no special training in the prevention of diseases. In nearly all such cases the women have been graduates of hospital training schools, and consequently have been well trained in bedside nursing. Notwithstanding their lack of special training in public health duties, much valuable work has been accomplished by these nurses, although it has always been clear to the Public Health Council that their value to their communities would be greatly enhanced by instruction in public health nursing as that specialty is now understood. The Council has established educational standards for public health nurses several years ago, but owing to the shortage of nurses during the war it was necessary to suspend these requirements for the time being. By resolution of the Council on November 9, 1922, the educational requirements for public health nurses employed in any public capacity in New York State were reenacted and made effective from January 1, 1924 in the following terms:

(1) They shall be not less than 21 years of age at the time of their appointment.

(2) They shall be registered nurses.

(3) They shall have completed a course in public health nursing approved by the Public Health Council.

Provided, however, that upon application in writing by the appointing power or by the nurse, these qualifications may be waived by the Public Health Council.

Correspondence Course

In order to offer trained nurses additional facilities and inducements to meet the foregoing requirements, and to fit themselves for employment as public health nurses, the Department asked the University and Bellevue Hospital Medical College to inaugurate in the fall of 1922 an extramural course in public health nursing on a plan somewhat similar to that of the correspondence course for health officers. This new correspondence course calls for four hundred eighty

hours of home study with one week in residence in one of the large urban centers for the purpose of lectures, conferences, field, and laboratory work. It is believed that with such a course conveniently available, there can be no plea of lack of opportunity to meet the educational standards set by the Public Health Council, which now constitutes the minimum requirement for employment as a public health nurse by a municipality.

The response to the announcement of this course more than justified the anticipation that there would be a demand for such instruction. More than five hundred applications were received, though it was possible to receive only half that number in the first class. There is every indication that this course, like the correspondence course for health officers, will become a permanent institution, and will materially contribute to the improvement of the quality of public health work throughout the state.

Institutes for Nurses

Instruction for nurses was also offered by the Department in 1921 in the form of institutes covering two weeks of intensive study of a number of subjects. Such institutes were held in New York, Syracuse, and Albany, and were attended by considerable numbers of nurses. As in the case of the health officers, however, this method proved too expensive when considered in relation to the number of students benefiting from the institutes, and the experiment convinced the Department of the superior advantages of the correspondence course in reaching larger numbers of the nurses actually at work in the field.

Maternity and Infant Hygiene

In expanding this year the field work of the Department in the protection of maternity and infancy, the new division of maternity, infancy and child hygiene faced the need of instructors qualified to lecture to mothers' clubs and similar local groups on these subjects. It was found that the average nurse in the public health field has not had sufficient instruction in maternity hygiene or in the methods of teaching mothers, their previous training in this respect comprising usually an obstetric service in a hospital and often including no pre-

natal work. An extension course for nurses in maternity hygiene was accordingly organized in August 1922, a special instructor of nurses being engaged to give lectures and demonstrations in various localities throughout the State. The nurses from the surrounding territory come in to a town where the lecture or demonstration is given at four weeks intervals. This course is open to registered nurses or graduates of approved hospitals, and is given particularly for public health nurses.

Courses in Sanitation

This year for the first time the Department has conducted at Albany two special courses, one for sanitary inspectors, and one for the operators of water works and sewage disposal plants. This was done in the belief that a number of such workers would take advantage of the opportunity to obtain brief special instruction in the scientific fundamentals of their work. Given more or less as an experiment the courses have proved quite successful with an enrollment of twenty-seven men in each case. They will probably be repeated next year and perhaps at other centers.

Annual Meeting

Another means by which the Public Health Law of 1913 contemplated the promotion of the instruction of health officers and nurses was found in the established custom of holding an annual conference under the auspices of the State Department of Health. Such annual conferences continuing over several days have been held in various parts of the state but usually at Saratoga Springs. They have become recognized as preeminent among meetings of health workers in respect to attendance, distinction of the addresses delivered, and practical results in keeping local health officers abreast of the latest developments in sanitary science. The most effective contribution made by the Public Health Law of 1913 to the success of these annual conferences was a provision making it mandatory upon every local health officer to attend, and requiring the municipality which the health officer serves to pay his traveling expenses on this occasion from public funds.

Recently the Public Health Council has undertaken a special examina-

tion of the equality of the instruction now being given to under graduate medical students, from whose number must inevitably be recruited the health officers of the future. Every licensed physician in New York state, graduated since 1907, when the present law went into effect, has had in his undergraduate work a course of instruction in hygiene equivalent to four hours a week for fifteen weeks. The exact value of this instruction as a qualification for performing the duties of the health officer is not easy to determine. In the opinion of the Public Health Council there has unquestionably been a **steady improvement** both in the content and in the method of presentation of the subject of hygiene and sanitation in the medical schools of New York state, as doubtless elsewhere.

The inquiry initiated by the Public Health Council made it clear that the special postgraduate courses for health officers do not differ materially in subject or time from those given to undergraduates; in fact, it was surprising to find such a coincidence in the curricula of two sets of instruction provided by different authorities for somewhat differing purposes. What is clear, however, is that undergraduate students have by no means the background of general medical education and practical experience to profit by such instruction to the same degree as the practicing health officers who take the postgraduate courses. The point of view and approach of the two groups of men are quite different. Undergraduates are usually not particularly interested in preventive medicine, since the medical curriculum is framed from the viewpoint of pathological conditions, individual morbidity, and curative medicine. On the other hand, the practicing physician seeking further to qualify himself for his duties as health officer attacks the course and absorbs the instruction in the light of his hard practical experience.

As a result of its consideration of this subject the Public Health Council believes that the medical schools of New York state should be encouraged to give a larger place in undergraduate medical curricula to instruction in preventive medicine, while at the same time continuing the established lines of post graduate instruction for the particular benefit of those physicians who have had little, or no training in public health while studying medicine.

Wherever possible, the department

has cooperated in the undergraduate instruction in public health given in the medical schools of the state. This is particularly the case at Albany where various officials of the head-quarter staff of the department have given such instruction to the students of the Albany Medical School, while arrangements have been made for section work in the laboratories of the Department. This year, in addition, the experiment has been tried of having the senior medical students systematically visit and study in turn each of the main division offices of the Department in order to obtain some knowledge of its routine procedures. As a result it is believed that these young men will go out into practice holding more vivid and accurate notions of the utility of all the various requirements which a modern central health administration lays upon the busy mind and hands of every practitioner of medicine.

Mental Hygiene in England

The rational treatment of mental disease is the subject of an article appearing in the issue of the London *Daily Telegraph* for July 13, 1923. This article is an account of a meeting held the preceding day in Caxton Hall under the auspices of the National Council for Mental Hygiene. Sir Courtauld Thomson, chairman of the Council presided. Among the speakers were Viscount Burnham, Sir Maurice Craig,—the well known neurologist—and Mr. Clifford Beers, founder in America of the National Committee for Mental Hygiene.

The article continues, "Mr. Clifford Beers . . . gave a striking address from the point of view of one who had experienced a mental breakdown." Following his address, "Sir Maurice Craig paid tribute to the high moral courage of Mr. Beers in using his own experience for the benefit of others."

The July 14 issue of the *Telegraph* contained a long editorial dealing with the problems discussed in their news report cited above. It said in part, "These are times which make heavy demands upon mental and nervous energy. It is surely plain to all—for private experience and the distressing cases which too often force themselves into publicity offer proof enough—that in the interests of the national vitality we must use to the full the knowledge which modern sciences has brought. That means—to put the case simply that public opinion must be taught to regard

mental disorder as preventable and remediable disease. The practical corollary, the provision of wholesome conditions of life, and of adequate opportunity of treatment and cure, will then be secured."

The National Council for Mental Hygiene, the organization now striving to awaken such public opinion in England was founded May 4, 1922. It is a member of the International League, and though an integral part of this new world-wide movement, the precise activities of the National Council now established in Great Britain include among others the following objects:

(1) The improvement of the mental health of the community by close study of the habits and environment of the people with a view to eradicating those factors which lead to mental disease, and to educating the public in matters which militate for and against good mental health.

(2) To promote scientific investigation of the causes underlying congenital and acquired mental disease with a view to its prevention.

(3) To secure a more important position for the study of psychiatry in the medical curriculum; to further the provision of facilities for the early treatment of mental disease; raise the standards of care in public mental hospitals; remove legal formalities which prevent early care of the afflicted; and to combat the prevailing superstition and ignorance regarding mental disorders.

(4) To study criminality, dependency, vagrancy, and prostitution, in so far as they are failures of adjustment by reason of mental defect or disease.

(5) The mental hygiene of child life in relation to education and parental responsibility.

(6) The Council hopes to be the liaison between all organizations interested in mental hygiene and as far as it can with advantage cooperate with them.

The mental hygiene movement is expanding rapidly. Reports in the daily press of other countries, such as those cited above, indicates that one of the most neglected classes of the afflicted are no longer to receive the neglect and even abuse that was their lot in generations past.

The exhaustion factor in the causation of tuberculosis is discussed by F. C. Smith in *Public Health Reports*. Night schools, overtime, excessive amusements, over indulgence, asceticism, "speeding up," dancing, and even outdoor sports in excess have serious effects and produce an exhaustion and a state of lowered resistance which promotes tuberculosis in the predisposed. Child labor either in factory or home the author regards as an important consideration.

KOTEX

Regular size, 12 for 65c
Hospital size, 6 for 15c
(Additional Thickness)

Kotex cabinets are being installed in women's rest rooms everywhere — hotels, office buildings, restaurants, theaters, and other places—from which may be obtained one Kotex with two safety pins, in plain wrapper, for 10 cents.

It means a great deal to women

Kotex is so convenient. So easy to dispose of by following simple directions found in each box. Kotex is so inexpensive. Cheap enough to throw away. Kotex is such a safeguard when one has planned to go away, to attend a game, a party, or the theater.

They are made exclusively of fine gauze and Cellucotton, the most effective absorbent material known to science. This makes them more absorbent—more comfortable, hygienic and safe—than old fashioned pads of birdseye or ordinary absorbent cotton.

It is so easy to buy Kotex. One asks for them by name. They are sold in drug, dry goods and department stores. It proves convenient to have a supply always on hand. The very first box shows how Kotex solves a difficult problem.

Sold everywhere—ask for them by name

INEXPENSIVE, COMFORTABLE, HYGIENIC and SAFE — KOTEX

The Fat Soluble Vitamin

(Continued from Page 688)

amounts of fat soluble vitamin in their food. The smaller allowance of fat-soluble vitamin has sufficed to support normal growth to adult size with apparent good health throughout the entire youth of the animals and often into early middle life, but in all cases has failed to support normal reproduction and successful suckling of the young. In the parallel group differing only in that they received a more liberal allowance of vitamin A, reproduction and lactation have been maintained and the numbers of young borne and successfully suckled have been fully normal. All of the twenty-two rats on diet low in vitamin A have now died, their average age at death being 369 days, corresponding to a little over thirty years of human life. Of the twenty-two which received the more liberal allowance of fat-soluble vitamin, seven are still living and the average age of all members of the group, living and dead, is already 701 days, corresponding to nearly sixty years in human experience.

These results make it plain that an allowance of fat-soluble vitamin sufficient to support growth at a normal rate and a good appearance throughout the growing age, was nevertheless below the optimum needed for full vigor. Particularly noteworthy among those on the diet low in vitamin A was the complete failure of successful reproduction in well-appearing young adults and the tendency of these to succumb to bronchial and lung troubles at an age about corresponding with that at which pulmonary tuberculosis so frequently develops in young men and women. The bacillus involved is different but the close parallelism in the susceptibility of lung tissue to infection at this stage of development appears very significant especially in view of the further observation noted above, that the vitamin A content of the lung tissue varies with that of the food.

In many respects we are doubtless only at the beginning of a full understanding of the relations of the fat-soluble vitamins to health and disease. But even our present knowledge makes it abundantly plain that a liberal supply of fat-soluble vitamin in the diet at all ages is an extremely important factor in the maintenance of a full measure of health and vigor.

You Will Enjoy Walking in these Comfortable Shoes

LATE afternoon—footsores shoppers turn to glance with admiration and envy. Who could look fresher and lovelier than a fashionably dressed woman swinging along in shoes as light and flexible as her step? All the vigor and grace of youth are in her carriage.

Comfortable Cantilever Shoes do away with tiring, shoe-bound steps. Flexible arches act in agreeable harmony with every demand of your supple foot arches, as the rigid arches of ordinary shoes cannot. This flexibility allows free play, giving to all the foot muscles the normal exercise that strengthens them sufficiently to hold the 26 small bones of the foot in their proper arched positions.

Cantilevers support, too. The snugg-fitting, flexible arches curve up when

you lace the shoe, to support the arch of the foot, gently and naturally, on the inner and weaker side. Your feet are enabled to carry properly the weight of the body without strain or restriction of the foot muscles. In trimly shaped vamps, your toes can straighten out in comfort. Natural lines and moderate heels afford a firmer purchase on the ground and the poise and grace which come from that.

Walking is so often a dreaded effort that tires the feet and frets the face. In Cantilever Shoes, it's a joy, an invigorating exercise that stimulates the circulation and brings a healthy color to the cheeks, such as you see on those smart American women who spend much of their time out-of-doors at the country club.

Except in New York and Chicago, only one store in each town is selected to sell Cantilever Shoes. If no dealer in this list is near you, write the manufacturers, Morse & Burt Co., 35 Carlton Avenue, Brooklyn, N.Y., for the name and address of a nearby dealer and a new booklet on the subject of feet and comfort.

Endorsed by women's Colleges, Women's Clubs, Public Health Authorities, Physicians, Osteopaths, Directors of Physical Education, Editors, Stage Celebrities and prominent women everywhere.

National Canners Association Passes Sanitary Regulations

The Board of Directors of The National Canners Association voted approval of the following rules and regulations governing factory sanitation at their meeting at Washington, May 24.

(1) All canneries shall be properly lighted and ventilated. When natural light and ventilation are insufficient, provision shall be made to supply sufficient light and ventilation, artificially.

(2) The walls and ceilings of workrooms shall be thoroughly cleaned and coated with light colored paint or other suitable material.

(3) Floors of wash rooms shall be kept clean. They shall be so constructed as to insure proper drainage and to prevent the accumulation of dirt.

(4) Gratings or slatted floors shall be provided in places where overflow or splashing is unavoidable.

(5) All washers, scalders, blanchers, and holding tanks shall be provided with a continuous water supply and an overflow, and shall be emptied and cleaned once each day, or as much oftener as is necessary to prevent souring or insanitary conditions.

(6) The supply of water and steam shall be ample to keep the factory in a sanitary condition. All water used on the premises for drinking, syrup or brine making, cleaning, washing or other purposes, must be safe and wholesome for the purpose for which it is to be used.

(7) Filling of cans with brine or syrup by submergence, or by means of a "dip tank" is prohibited.

(8) Necessary drainage shall be

provided to remove all sewage and other liquid waste in such a manner that it will not become a nuisance.

(9) The cannery and surroundings should be kept free from accumulated waste and rubbish. All peelings, skins, cores, etc., shall be removed daily.

(10) By-products, such as pea vines and corn husks, unless removed from the premises daily, shall be stacked or placed in silos separate from the building. The stacks or silos shall be properly drained.

(11) Canneries shall be operated in compliance with state, or federal sanitary laws, applying to such canneries.

(12) Fresh fruits, or vegetables shall be washed before being canned, except cabbage, from which all damaged or soiled leaves shall be removed, and corn and berries, which shall be washed when necessary to secure a

clean product. Decayed and damaged parts shall be trimmed from all fruits and vegetables.

(13) Boxes, tubs and tanks for holding raw materials, and boxes, crates and other containers furnished to the growers, shall be kept in a sanitary condition.

(14) Tables, floors, utensils, conveyors, and machines shall be cleaned after each day's operations, or as much oftener as is necessary to prevent souring or insanitary conditions.

(15) Pails, pans, or similar utensils used for the preparation of food for canning shall not be used for cleaning up purposes.

(16) The cans and covers shall be stored in such a manner as to prevent contamination and shall be clean when used. Empty cans shall not be kept uncovered in the canning room floor. The filled cans should be clean when shipped.

Child Health Association

THE American Child Health Association's first annual convention in Detroit, October 15 to 17 will draw together some of the most eminent child health authorities in the United States and from other nations as well.

Among the chief speakers will be Herbert Hoover, president of the Association, who will deliver the opening address; Dr. George E. Vincent, president of the Rockefeller Foundation; Mrs. William Brown Meloney, author and editor, and a director of the Association; Mayor Frank E. Doremus, of Detroit; Dr. Haven Emerson, professor of Public Health Administration of the College of Physicians and Surgeons, New York; Miss Maud Brown, a child health education specialist of nation-wide reputation; Dr. William J. French, director of the Fargo, N. D., child health demonstration; A. D. Jamieson, secretary and scout executive of the Detroit Council of the Boy Scouts of America, and Monsieur J. Maquet, Directeur-General de l'Oeuvre Nationale de l'Enfance, and Secrétaire de l'Oeuvre Nationale des Orphelins de la Guerre in Belgium.

Some of the topics for discussion and papers to be read will deal with community programs for child health, how the general public can bring about better co-ordination of community activities for child health, the workers in child health education and their duties, practical methods of teaching health to children, and the

newer phases of public health nursing, and the health of the child in relation to athletics and physical training will be discussed.

The convention, as the association's first, is expected to be the forerunner of others which will serve annually to bring together the child health experts of the country for the suggestion and solution of subjects which will raise child and material health in the United States to a higher plane. Since its organization in January, from a merger of the old American Child Hygiene Association and the Child Health Organization of America, the association has grown rapidly until now the membership numbers nearly five thousand and extends to many foreign lands.

The aims of the Association are to achieve this child health improvement through helping communities to increase their own health protection to a maximum, through teaching, literature, the founding of scholarships for doctors, teachers and nurses in health work, and by other means designed to increase the health knowledge of parents and children.

Herbert Hoover is president of the Association. Dr. L. Emmett Holt noted child health authority, is first vice president; Courtenay Dinwiddie is general executive, and Ella Phillips Crandall is associate general executive. Headquarters of the Association are at 532 Seventeenth Street, Washington, and executive offices 370 Seventh Avenue, New York City.

When peristaltic inactivity is the complication—

DURING protracted illness, the physician is often faced with the problem of inducing peristalsis without causing intestinal disturbance.

In such cases, fresh yeast is valuable not only for its laxative effect, but because it actually aids the processes of digestion and intestinal absorption. "It stimulates peristalsis and at the same time softens the fecal masses" is the conclusion of the investigators who recently completed an exhaustive series of tests on the effects of fresh Fleischmann's Yeast.

Not only does yeast assist regular intestinal activity, but

its vitamin content is highly beneficial, and experiments have shown that it induces a definite leucocytosis.

Best results are obtained by eating one cake half an hour before a meal or the last thing at night—followed by a glass of water. If desired, the yeast may be first dissolved in water, milk, or fruit juices.

A new authoritative book: Written by a physician for physicians. This brochure discusses the manufacture, physiology, chemistry, and therapy of yeast. A copy will be sent you free upon request. Please use coupon, addressing The Fleischmann Company, Dept. Y-24, 701 Washington Street, New York, N. Y.

State Institution for Crippled Children

(Continued from Page 690)

it will not be very difficult to secure appropriations when our legislators know how little has been done along these various lines.

Character Formation

We must instill in these children the desire to work and support themselves, and training along these lines may possibly be of more consequence than mental education. It will accomplish nothing if we train a child and have him become proficient along certain lines if he has not the desire to use his talents. We aim to teach by example, having those in charge who will by association and attendance teach the child the good he should know. Religious societies have been a great help to us in many ways. Children are imitative, and are impressed by those with whom they have constant contact. The child must not only have education but must also be taught to use his ability in the right way. Recreation has a great advantage in educational lines. Outside influences are brought to bear, new things are seen and well remembered. We have great help from the outside through music-clubs, reading-clubs, theaters, and private individuals, and many an entertainment is long talked of, actors imitated, new mechanical toys invented, and many new feats performed by the little people of the state hospital on the incentives offered by recreational opportunities.

Traveling Clinics

A traveling clinic can do best work in an educational way and many suggestions can be given by the clinic. Parents in distant communities are taught that there is help for most physical deformities. The examination given the individual can be of great value to an established institution, deciding who can be benefited by treatment in that particular institution. The clinic can also cooperate with local physicians and visiting nurse associations, securing the best possible care of a given case. As far as real treatment in our experience is concerned in an orthopedic way, the traveling clinic is a failure among the indigent.

Social Service

Visiting nurses connected with an institution are most valuable. Home surroundings are noted; instruction is given to the parent or patient who

can but feel and know that the institution is still interested in their well being and future care; also by the aid of competent nurses the institution can earlier be relieved of the care of the individual, knowing that supervision can be carried on with some success at home.

The State Care of crippled children is a most laudable undertaking. New York, Massachusetts, Nebraska, and Iowa along with Minnesota maintain separate state institutions for the care of crippled and deformed children. Many other institutions in the United States, which depend upon private subscription, are doing valuable work in the education and treatment of crippled children. The recent Shrine movement of establishing hospitals throughout North America is a noble work and the benefit secured through these institutions will be most valuable. An institution caring for the indigent crippled and deformed children is the most constructive institution the state can maintain in caring for its dependents.

States that have no such institution can certainly profit by studying the institutions already established. We feel that the greatest good can best be obtained through an institution, that is, a hospital and school combined, where the child can receive instruction and training along with his medical and surgical care. The discharge from this institution should be only when the child is able to compete with and in the great part associate with normal children, or when the individual has become self-supporting through some trade or occupation taught in the institution. A hospital of this type may not be ideal for other states, but we feel sure that in Minnesota the greatest possible amount of money appropriated goes directly to the care of the crippled child. Orthopedic treatment we feel sure can most successfully be carried out in an institution. Education in the home or school not equipped for special training in a greater number of cases can be of little value.

Occupational Anthrax in Germany

INFORMATION concerning anthrax infection in industry and agriculture and on the disinfection of wool containing anthrax spores collected by the International Labor Organization, brought up to the year 1921 is summarized in the August issue of *The International Labour Review*. Anthrax among animals is defined by statute as an infectious disease in all cases, and its occurrence is made notifiable. Likewise among human beings sickness or death by septic anthrax, and all suspected cases, are made a matter of record and observation. Sanitary police regulations deal with the disposition of carcasses of infected animals, and infected stables are required to be disinfected with lime.

A Prussian order of 1902 deals with the danger of anthrax from skins, and provisions on accident prevention in 1910, carry rules to protect tannery workers against anthrax. An imperial order in 1909 prohibits the employment of young persons in factories where use is made of machinery for opening, dusting, or working up animal hides. Workers in brush and hair factories have been protect-

ed since January, 1899. No special measures apply to the wool industry, but power is given to undertake precautionary measures if necessary.

The total number of cases of anthrax among animals in Germany over the period 1912 to 1921 was 30,269. There were 1,575 cases of human anthrax reported over the period 1910 to 1921, the highest number occurring in 1910, and the highest percentage of deaths from this cause being recorded in 1917.

Classified by occupational groups, the incidence was as follows: Agriculture, 51.2 per cent; hides and skins, 36.9 per cent; hair, bristles and wool, 8 per cent; miscellaneous, 3.9 per cent. Cases were reported from ninety-two out of 125 tan yards. Only three cases were reported in the wool industry over a period of ten years.

The record shows that in Germany anthrax is becoming rarer in agricultural occupations. It has also decreased enormously in industrial occupations, this being attributed largely to the great decrease in importation of material from abroad.

Proper Mechanical Treatment for Weakened Metatarsal Arch

The two predominating symptoms of Weakened Metatarsal Arch are Metatarsalgia and Callouses on the sole over the Metatarsal region. This condition is easily recognized by the depression of the Transverse Arch anteriorly or at the base of the Metatarsal bones. The dome-like arching is obliterated and painful callosities or corns form over the depressed Metatarsal heads. The foot broadens, the toes become dorsal flexed. Bunions appear at the First and Fifth Metatarso-Phalangeal articulations. Digital nerves become impinged and severe cramp-like pains are experienced through the toes. This is known as Morton's Toe. These conditions, Doctor, are quickly relieved and the cause effectively corrected by the use of

Dr Scholl's *Corrective Foot Appliances*

These appliances are especially designed and constructed to restore the Anterior Arch, remove abnormal pressure and permit full freedom of motion to the entire foot. There is a different type to meet each individual requirement.

Dr. Scholl's Corrective Foot Appliances are sold and fitted by leading shoe dealers in every community who have been instructed how to properly apply correctives to the foot and shoe.

The Welfare of Children

(Continued from page 698)

land as free pasture for the employees' cows. Every child must have milk and at 15 cents a quart, not many of our big families could give their children milk to drink three times a day or even once a day. Yet with free pasture, most of our families can and do, own a cow.

We believe that one of the greatest evils we have to contend with in cotton mill towns is snuff. If there is one subject we preach on morning, noon and

night, it is snuff. When we first came to Alabama, we had never seen any one use snuff—and being stopped on the street by a woman and asked to tell her something to do for a sore in her mouth. She opened her mouth to show us the sore, her lower lip was full of snuff—and seeing the black cake covering her gums and lip we thought of a gangrenous condition and offered to take her to see a doctor. She laughed, tried to spit the snuff out, and told us the sore was in the roof of her mouth. We have seen mothers put the snuff sticks in the baby's mouth to quiet him and little children come in and say, "Ma, I want a dip," and the mother hands her a box of snuff and the family brush or dipping stick, which is made from dogwood or sweet gum by chewing the end of the stick until it is soft and makes a sort of brush. We are thankful to say the snuff habit is going—very few of our young girls use it, and our mothers, many of them have quit, and most of them forbid their children to use it.

We have several organizations in our town that are doing a wonderful work toward keeping the children physically fit, and develop them into 100 per cent boy and girl that will take their place in the future, 100 per cent man and woman as God planned and meant them to be.

The following facts have been supplied by mountains, and though the sum-

plied by the author of the above conference paper showing the scope of other health and welfare activities of the company.

The mill village is most ideally situated for health. It is surrounded

house having a garden, or chicken run and cow pasture renting for three dollars per month.

The company does not require a health certificate when employing new hands, yet in the house to house

visiting of the nurse and doctors those having contagious or infectious diseases are soon spotted and are excluded from the mill.

All children under eighteen years of age wishing to work in the mill must present a school certi-

Lake and bath house in mill village.

mers are warm, yet we have an almost continual mountain breeze. The nights are cool and refreshing and a light blanket is always comfortable before morning. The village is amply shaded by beautiful old forest oaks, some of which could tell of happenings a century ago. The winters are mild and pleasant, the city being protected from the north wind by Lookout Mountain. We have lime, freestone, and iron drinking water. The very best of the drinking waters is piped directly to the yards of the cottages.

The operatives are supplied with very cosy convenient cottages, all or most of them of different design and contrasting colors. They are painted inside and out about every four years, no two in the same block alike. Each house has a veranda and most of them have large cool halls. The object of painting and decorating and using a different design in construction is to give the appearance of real homes rather than houses for "mill hands."

The Dwight Manufacturing Company owns all houses and property in the mill village, consisting of about five hundred houses available to employees, and others connected in some capacity with the Dwight Company, all renting for one dollar per room per month. The houses have from three to seven rooms; a three room

house showing applicant to have passed to the sixth grade in public school. He must go before the doctor for examination. He must be free from disease and up to normal in weight according to age and height. An applicant underweight is advised as to diet, sleep, etc.; he is warned against excessive use of tobacco, coffee, tea, and dope, and is sent home and told to report again in two weeks. They are usually very anxious to work and will obey health rules in order to gain the number of pounds required to enter them as a regular on the pay roll.

One very pale, undersized little fellow who was sent home to eat and grow, came back in two weeks with a five pound weight in each pocket and was very much hurt when asked to remove his coat without a chance of transferring the weights to his trousers pockets before getting on the scales.

The Dwight Manufacturing Company employs about eleven hundred people, about 40 per cent being women and girls, about 60 per cent being men and boys. About thirty boys and girls between fourteen and sixteen years are employed eight hours per day. The mill however runs ten hours.

Equipment for Community Work

We have a community house where the young folks, properly chaperoned, can have their parties and entertain-

Behavior of Stanolind Liquid Paraffin to Intestinal Toxins

DR. J. H. KELLOGG, in the New York Medical Journal, states that "One of the very interesting features of the many sided activities of liquid petrolatum (Liquid Paraffin) is its behavior toward intestinal toxins.

"These toxins are of bile acids, and alkaline wastes, excreted by the intestinal mucous membrane, and of a great variety of ptomaines and toxins produced through bactericide action in the colon and small intestine.

"In cases of incompetency of the ileocaecal valve, it (Liquid Paraffin) is a highly active solvent and readily dissolves these waste and poisonous substances, many of which are more soluble in liquid petrolatum (Liquid Paraffin) than in water. This oil, itself not absorbable, thus takes up a very considerable portion of these toxins and prevents their absorption."

Stanolind Liquid Paraffin (Heavy) being of unusually high viscosity passes slowly through the entire length of the alimentary canal and is sufficiently retarded in its action to permit a very complete absorption of these intestinal toxins.

Stanolind Liquid Paraffin (Heavy) is a new medicinal petroleum product, having a viscosity of 300-310 Saybolt at 37.7 degrees C (100 degrees F); specific gravity—0.891—0.895 at 15 degrees C (59 degrees F), and is meeting the especial need of those physicians who, previous to its introduction, avoided mineral oils of domestic origin.

ments. The house is equipped with a large kitchen where the girls or women can cook and serve dinners and where our girl scouts go for their cooking tests. The bath room has about five showers and dressing rooms. The reception hall is large

and airy and yet we find it inadequate for the large crowds that attend functions given there. We have provided and equipped tennis courts and basketball courts, and acres and acres of the great out-of-doors for all sorts of sports.

Handling Non-Resident Venereal Disease

IN a mid-western city of approximately two hundred fifty thousand population a movement was initiated to abolish the municipal venereal disease clinic and turn it over to the county. The matter was brought to the city council by a group of citizens who advocated this plan on the natural though non-altruistic plea that the clinic was doing too much for non-residents. One question which arose was "What arrangements are made in venereal disease clinics supported by a municipality, for transporting non-resident patients to their original homes?" The public welfare commission of the city sought advice from the American Social Hygiene Association on this point; since the Association did not have in its files specific information regarding practice in this matter, the question was referred to the health officers of a group of eight cities, six of similar population size in different states, one of similar population in the same state, and one the largest city in the same state.

Four cities gave direct replies to the question referred. Three of these stated that transportation was never provided. The fourth city described arrangements for transportation as follows:

After having taken these precautionary measures, (treatment and quarantine, if necessary,) we then attempt to communicate with the relatives, or if necessary with the authorities where these patients are residents. In many of these cases the relatives or authorities have instructed us to send them back to their homes and they have remitted to us expenses incurred in such transportation. In a few instances, we have been compelled to call upon the Associated Charities to provide such transportation. As far as we are concerned, this question has never been raised by any of our tax-payers and I doubt whether any serious objection will ever be raised, because we are keeping in the foreground our main argument, viz., we must protect our own people against infection.

Five of the health officers commented upon the general question as to the handling and treatment of non-

residents as follows:

In regard to non-resident patients being treated at our clinic I may say that we treat all patients who apply to us, whether residents or non-residents.

Inasmuch as this clinic is a co-operative affair between the city and state health departments and the U. S. Public Health Service, very little attention is given to the place of residence of those receiving treatment. Nearly all patients donate a reasonable amount for the treatment given.

Our policy here has been the same as with other communicable disease cases, viz., first, we must protect our own people, therefore, we give free treatment if necessary, to non-residents, or if we believe that they will continue to violate our ordinances by exposing others to the disease, we place them under quarantine.

If a non-resident presents himself to any of our clinics we treat him. Why should we discriminate against any city. We have even stretched our rules so that if anyone from a nearby town who cannot afford to pay for treatment applies for treatment we will treat the patient believing that we are thereby protecting our own citizens, as well as the citizens of the town wherein the patient is resident. If a municipality is so narrow that it won't treat a patient with an infection who can't get treatment elsewhere, it ought to establish a few churches for the teaching of the message of the Master and it ought to lock up its reservoir and not give a thirsty man a drink.

The other health officer states that after all non-resident cases do not constitute a large proportion of the cases handled by the clinic even when they are admitted to treatments without question. The importance of this comment is increased by the fact that this city is the largest one of the group, having a population of about eight hundred thousand. His statement is as follows:

So long as a case is a danger to public health, namely, in the infectious stages of these diseases, we consider him eligible for free treatment if unable to pay for same. In spite of the claims that large numbers of cases come from outlying districts to secure the benefits of treatment in the clinics here our own experience does not confirm this. . . . As we are subsidized by the state par-

tially through the free distribution of arsphenamine, this would more than offset, probably, the responsibility of caring for the non-resident patients.

In contrast with these comments from five cities as to the importance and practicability of treating non-resident cases we have the following comments from the health officers of two other cities of the group surveyed.

In our municipally controlled venereal disease clinics, non-residents are not received except in an emergency. We have had to be extremely strict in order to prevent surrounding communities filling our City Hospital and clinic with non-residents, not only venereal cases, but also those of scarlet fever, diphtheria, etc. We certainly cannot afford to maintain a hospital for other communities which are just as well able to pay for hospital service as we are

In dealing with non-residents who present themselves for treatment at our clinics, would say that the rules of the hospital are very rigidly enforced and we do not receive any clinic patients who reside outside of the limits of the city. All cases applying for clinic treatment are investigated by the social service bureau of the hospital, their residence in the city checked up, etc. We have had considerable difficulty in the past in handling this phase of the hospital admissions but at the present time things are running very smoothly and I believe that the residents of the surrounding cities and towns have arrived at a proper understanding of our attitude in the matter and it is only occasionally that a non-resident will apply for admission for clinic treatment, when of course, as stated, above, he is refused. This applies not only to the type of case mentioned in your letter but to all cases.

Only one health officer commented upon the objection of tax payers to paying for the treatment of persons careless enough to become infected with one of the social diseases. He stated his comment as follows:

It seems to me that the argument, from the public health standpoint, that free treatment should not be given to those careless enough to become infected with a social disease, is absurd. Were it valid, it would be as well to dispense with all Venereal Disease Clinics.

Child Labor on the Increase

Grace Abbott, chief of the United States Children's Bureau, stated before a sectional meeting of the Home Economics Association in Chicago, August 1, that child labor in the United States is increasing. One million children between the ages of ten and 16 years were employed in January, 1920, she said. A decrease was registered in 1921, but reports from twenty cities indicate marked increases for 1922, some as high as 100 per cent, a general increase of 57 per cent being shown.

The Railway Accident Problem

(Continued from page 692)

new employees along safety lines and also the necessity of having a foreman or a supervisory official who recognizes the importance of safety as it should be applied in the course of railroad operation.

Analysis as to the causes of accidents to employees brings out more and more the importance of giving careful consideration to contributory factors with the thought of applying such remedies as will eliminate the causes. When accidents resulting in personal injury or death are not accepted as inevitable in the usual daily events and when those in charge of supervision understand that they are expected so to educate their forces and direct their work in such a manner that accidents do not occur, the result will be practically an elimination of all accidents which have been classed as inevitable.

The railroad accident problem not only involves the railroads and their large army of employees but it involves the public as well. Not only are the railroads interested in a reduction of accidents in which they are involved but the public, including the large body of railroad employees are also vitally concerned and to this extent the entire plan involves society. So we may assume that the general scope as it applies to accident prevention has the approbation of the American public and that passively, at least they are lending their support to this movement.

The fact that in the United States during the year 1920 there were seventy-six thousand people killed and approximately two million injured through accidents should be sufficient to cause the American people to halt and take an accounting of steps necessary to curb this enormous life wastage.

The enormity of the number of people being killed and injured daily in this country through accidents is brought out by comparisons with the number of our United States soldiers, sailors, and marines killed and wounded during the nineteen months in which we were involved in the World War. During this period there was an average of three thousand killed and about six thousand wounded per month. Whereas in America during the second year following the close of the war peaceful pursuits resulted in approximately sixty-three

hundred people killed and one hundred, sixty-five thousand injured each month. Putting it another way, more than twice as many people were killed per month during peace times and more than twenty-five times as many injured as soldiers killed and wounded during the same period of time during the World War.

The call for cooperation of the American public to the end that human life and limb will be conserved for the use for which it was intended should meet a hearty response for the results obtained affect society as a whole. While casualties to railroad employees concern the public to a certain extent, yet the public is more vitally concerned in the elimination of that class of accidents with which they are in daily contact. Surely it is a matter of vital concern that there are approximately eighteen hundred people killed and five thousand injured in the United States each year as a result of highway crossing accidents. During the five year period ending with 1921 the number of casualties resulting from highway crossing accidents with automobiles as compared with the total number of all classes of highway crossing accidents have increased from 50 per cent to 80 per cent. The one element which has been the principal factor in this increase is the large increase in the use of automobiles. During the same period the number of licensed cars was increased about 125 per cent. It is a well known fact that grade crossing elimination is a real remedy for the prevention of this class of accidents, but it is also well recognized by all right thinking people that it is a physical and financial impossibility to eliminate these crossings within the next several generations, and, therefore, we must accept the situation as it exists and try to apply a remedy that will meet this situation.

This is a field that has wonderful possibilities. It is a field in which success cannot be hoped for unless there is full cooperation between the railroads and the public. The railroads are endeavoring insofar as is possible to keep the physical condition of the crossings in such shape that accidents from this cause can be minimized.

The railroads appreciate that they have a duty to perform and I feel

justified in saying that they are as a general rule endeavoring to carry out a plan which will serve to reduce grade crossing accidents. They are making special efforts to eliminate such obstructions to view as are within their province to do so. They are trying to educate those to whom is entrusted the responsibility of protecting the crossings so that they will render the service expected of them; they are making special efforts to have the enginemen give proper warning signals upon approaching these crossings; in fact they are going upon the assumption that not only do they have a duty to perform but that they must go to the public with clean hands and in good faith ask for their full cooperation.

Since we will have approximately thirteen million licensed automobiles in use in the United States during 1923, it behooves all concerned to concentrate their efforts and energies to the end that the great sacrifice will not continue. The best results possible are to be obtained only from special appeal to the users of the highway.

The motorist should be aroused to his full duties in the premises, his conscience should be awakened to the enormous life wastage resulting from automobile accidents. We must appeal to his better manhood to join with us in our effort to stamp out the demon carelessness. He should know that fatalities resulting from automobile accidents are increasing in this country at the alarming rate of more than twelve hundred per year and that in 1922 there were approximately thirty-five deaths per day from this cause and that of the total number of railroad grade crossing accidents 80 per cent are with the automobile.

These facts ought to be sufficient to point to the motorist where the principal trouble lies and should be sufficient proof to justify the statement that most of these accidents can be eliminated if the driver will at all times exercise his faculties and use good judgment in approaching and passing over these crossings.

During the five years ending December, 1921, there was an average of three hundred passengers killed and seven thousand passengers injured each year and considering that the railroads of this country carry ap-

Sterilizer Combination for Clinics and Industrial First-Aid Rooms

YOUR first aid room or clinic needs more than a single sterilizer. An emergency may come any day that will demand quick facilities for hot or cold sterile water, as well as a dressing and instrument sterilizer. Supply your staff with a Castle combination to give the maximum utility.

This No. 1014 has instrument, dressing, and hot and cold water sterilizer. Other models with fewer units. Electric, gas, steam or alcohol heat. Send for catalog "H."

it stands alone

proximately 962,000,000 passengers per year which is more than nine times the entire population of the United States it will be observed that the percentage of casualties from this cause is relatively low. The point desired to be emphasized in this connection is that in the handling of passengers the railroads are more in a position to assume a substantial portion of the duties requisite to the care of those about their property or riding upon their trains, this duty being to a large extent one on the part of the railroads (although the passengers are required to exercise proper care and caution for their own safety). This enables the carriers more completely to carry out the safety plan and in consideration of the large number of passengers handled, this record is one of which the railroads have just reason to be proud.

Mutual Responsibilities

The mere fact that there is more of a divided responsibility between the railroads and the users of the highway serves to increase rather than decrease the number of railroad grade crossing accidents. The users of the highway fail to appreciate that they have an obligation resting upon them to know that the way is clear before attempting to cross the tracks and failure to exercise their faculties to this extent results a great many times in a serious misfortune.

The basic foundation upon which our government was established is that safety shall be enjoyed in the pursuit of freedom and liberty. In a small measure the things we hope to accomplish as a result of the blending of our efforts with the support of the people who are most vitally concerned will serve to further the principles which have descended to us as a priceless social heritage. Such measures will intensify the spirit of safety and result in fewer deaths and injuries from all causes and to this extent we will aid in the retention of the freedom which is a part of our life.

It is, therefore, important that we enter into this fight not with an over-confident feeling but with sufficient confidence in the justice of our cause that we will have no thought of defeat. We should concentrate our efforts and move forward with a full determination to win. If we do this our efforts will be rewarded with success and we will not have labored in vain. This field to which we dedicate ourselves is one that is noble and one that will appeal to the innermost conscience of our countrymen. Our reward will be in the knowledge that

we have been instrumental in conserving life and limb.

Through a unity of purpose and the concentration of our energies together with the cooperation of those most vitally concerned we can have the assurance that we have had a part in a great plan which has rendered an invaluable and lasting service to mankind.

Nursing and Nursing Education in the United States

The report of the Committee on Nursing Education appointed by the Rockefeller Foundation was published in *THE NATION'S HEALTH* (July, 1922, Vol. 4, p. 408) and has been extensively discussed in these columns and elsewhere, during the past year. The volume here reviewed includes the results of the exhaustive study by Miss Josephine Goldmark, upon which the recommendations of the committee were based. This study deals with the numbers and types of workers needed for the care of the sick and for the tasks of health education, and presents actual field studies of the daily work of the public health nurse which clearly indicate the need for a broad and fundamental nursing, training to prepare for the teaching of health in the home. Miss Goldmark then passes to the actual status of nursing education and the studies made by her staff of observers as to existing conditions in hospital training schools will prove illuminating in the extreme to all not already familiar with the uneven and unsatisfactory nature of such education. The remedy of course is an adequate endowment of nursing education and the case, presented by Miss Goldmark and set forth by the committee to which she reported, is so convincing that it has already led to the establishment of a university school of nursing supported by the Rockefeller Foundation at Yale and to the consummation of plans for an endowed university school in Cleveland. It is to be hoped that this message will receive prayerful consideration in all the large cities of the country. We should have not one, or two, but a dozen, well endowed institutions of this kind in different parts of the country if the need for leaders in nursing and nursing education is to be met.

The Macmillan Company, New York, 1923.

The National Association of Colored Graduate Nurses met in sixteenth annual convention in Chicago in August with an attendance of 122 delegates.

New Jersey Regulation of Food and Beverage Stands

The department of state police, charged in New Jersey with the inspection of roadside stands from which food is served, have reported gross violations of the state sanitary code, chiefly, due to ignorance of the required conditions on the part of the stand operators. The New Jersey regulations for the conduct of booths, stands, and stores where foods and beverages are served are as follows:

(1) No food in a state of putrefaction or decomposition shall be served.

(2) No chemical preservative shall be used in milk or meats.

(3) No false or misleading statements shall be made upon labels of containers of food or beverages. No false or misleading statements shall be made upon signs or posters nor upon the booths regarding the foods or beverages served.

(4) Glasses, dishes, knives, forks, spoons, cooking utensils, and receptacles, in which foods or beverages are stored or served shall be washed thoroughly with soap or washing powder and water and then rinsed in clean water after use.

(5) Foods which are not packed in tight containers shall be protected from contamination by dust, dirt and flies.

(6) If perishable foods, such as milk and meats, are served, ice boxes ample in size shall be provided. Ice boxes shall be kept in a clean condition.

(7) All waste liquids shall be conducted from the booths or stand and disposed of in such a manner that a nuisance will not be created and in such a manner that a water supply is not polluted.

(8) All garbage shall be removed from the premises daily and disposed of so that a nuisance is not created.

(9) Clothing worn by persons engaged in preparing or serving foods shall be clean.

(10) Water shall be procured from some source which is not polluted.

(11) If privy vaults are maintained, they shall be constructed so that flies cannot gain access to the excremental matter. If privy vaults are maintained within one hundred feet of any spring, stream or well, the vaults shall be constructed so that they are water-tight.

(12) Human excrement shall not be allowed to remain upon the surface of the ground and shall not be buried within one hundred feet of springs, streams or wells.

Minnesota has provided for the establishment of a psychopathic department of the Minnesota General Hospital and has appropriated money for its construction, equipment, and support.

Senate Bill 22 of Ohio, effective July 29, makes the state narcotic laws conform to the Federal statutes.

Anthrax and Tetanus Are Seldom Found in Range Sheep

Armour's Sterile Catgut Ligatures are made from the intestines of range lambs. Regardless of that, as much care is taken at every step of processing as could be taken with "casings" gathered here and there, by manufacturers whose only facilities are the open market. We, being the source of supply, select the material that goes into surgical strings and, knowing its destiny, take every precaution to insure great strength and sterility.

We offer non-boilable sterile catgut ligatures 000, 00, 0, 1, 2, 3 and 4 plain, and the same in 10, 20 and 30 day chromic. These ligatures are very flexible. Also the same sizes and kinds in the boilable grade and iodized catgut ligatures, 000, 00, 0, 1, 2, 3 and 4.

interest you

WHEN Pasteur made his great discovery which brought about the Pasteurizing of milk, it was a tremendous scientific step toward greater purity. When Heath made his remarkable discovery of Heathizing Ice-Cream, food scientists acclaimed it as an equally momentous achievement.

HEATHIZATION is the newly discovered method of making ice-cream in an atmosphere of purity and cleanliness. In making Heathized ice-cream, the ordinary air is driven out of the freezers and replaced with a clean, pure and sterile atmosphere. The result is a more delicious tasting and better flavored ice-cream. The texture of the ice-cream made this way is richer, more creamy, more appetizing.

UT, above all, Heathization is a sanitary precaution. It protects the purity of ice-cream. There is a manufacturer of Heathized Ice-Cream in your city, so look for this "Sign of Purity" when buying ice-cream. If your dealer hasn't it, ask him to get it for you, or write us for further information.

Three New Services of Life Insurance

(Continued from Page 696)

interests. Here we have a direct business proposition, tying up annual medical examinations and public health with life insurance. Here we have the public health of the future on a sound economic foundation.

The Call to Service

The human race needs and now is calling for a longer and stronger life. Public health and medicine can take care of the physical technical problems involved; but only life insurance companies can furnish the sound financial business foundation for this physical regeneration of man. This call on life insurance companies is a call to solve today's greatest physical problem, a huge problem, which only the financial knowledge and organization and the knowledge of the actual facts of life, death and disease possessed by life insurance companies can solve.

Even an attempt at its solution means publicity and education of the best on these lines; but a successful solution means the greatest advance for mankind ever yet achieved by man.

1. Fiske gives the annual cost of sickness per head of the population as thirty dollars, which is one hundred and fifty dollars per average family or about \$270,000,000 to \$300,000,000 annually in Canada. This item yields some very interesting consequences. Contrary to the general belief, "doctors' bills" form a very small item in cost of sickness. The total of the physician's share of the bill averages, on pre-war figures, only one dollar per head, five dollars per family, or \$9,000,000 for all Canada. If we treble this amount for advanced rates since the war, still the physician receives only 10 per cent of the total cost of sickness, or \$27,000,000 out of a total cost of two hundred seventy million dollars. Periodic examinations of everybody at only five dollars per head (which is but one-sixth of the cost of being sick), would yield the medical profession \$15,000,000 from the same source alone, as compared with a present total of nine million dollars or even of the exaggerated figure of twenty-seven million. Moreover, the improved financial status of the public due to earlier treatment, lessened sickness, etc., would make collections better. Finally, note that this new \$15,000,000 would be in addition to whatever income the physicians would still receive for therapeutic services; which would probably be about as much as present; not because sickness would not be reduced but because much sickness not now treated would come to light. From 30 to 60 per cent of sickness requiring medical aid is now never treated. In other words, the reduction in sickness now treated by the medical profession would be, in part at least, offset by the increase in treatment of sickness now escaping attention. Periodic examinations would thus be of immense economic value; (a) to the public, in reducing the total cost of sickness to any, one hundred million dollars, instead of three hundred million as at present in Canada, and, (b) to the medical profession, in yielding to the latter from 40 to 50 per cent, \$40,000,000 to \$50,000,000, of the future reduced cost, rather than 10 per cent more or less, \$27,000,000 to \$9,000,000 of the present much greater cost. (Hill, Canadian Medical Association Journal, January, 1923, page 72).

2. (Knight, Medical Director, Metropolitan

Life, New York, December 7, 1922): "The insurance medical examination puts into our hands an opportunity for better service which we have not developed at all. Every year the records of our companies show from 7 per cent to 10 per cent of applicants rejected or postponed for insurance. The reason for this man's attitude is often one of angry disappointment, but his second reaction is one of enquiry into his state of health and of determination to do all within his power to administer himself physically fit. The psychology of the situation is entirely a favorable one for performing constructive, remedial work. . . . We should, I believe, work out a way of informing rejected and postponed applicants of the causes for rejection or postponement in every case where we can safely do so. . . . We might, too, carry through our stroke and suggest that he place himself under proper medical supervision and give him reasons to believe that he may become insurable in the future. . . . But this is only the beginning. It is the habit with some of us, in our everlasting drive for new business, to forget those that are already insured with us. . . . Medical examinations are an expensive part of the cost of life insurance administration. We can easily make them worth all that they cost, and a great deal more, through the simple expedient of the periodical follow-up examinations of the persons insured with us. Fortunately, this matter is no longer in the experimental stage. . . . We were able to show that those who were examined in 1914 and 1915 for a period of five years following the examinations, showed a mortality 28 per cent more favorable than that for the entire ordinary department in the same years. We further calculated that the saving in mortality gave a return of \$2 for every \$1 expended for the insurance examinations. . . . Every year added to the life of an adult is an addition of \$500 to the total national wealth."

3. A recent study (by H. W. Hill) of the census return of 1917 for the registration area of the United States (the latest and most complete figures then available—no similar Canadian statistics were to be had), show that of about a million deaths, approximately one-fourth were from diseases having unknown causes ("Cancer," for instance)—or indefinitely stated "diseases of unknown cause" (or unstated "miscellaneous" or similar terms). The remaining 750,000,000 deaths, from known and definitely stated causes, showed that infectious diseases, various kinds of violence, accidents, homicides, suicides, poisonings by drugs, chemicals, etc., were omitted as not properly "diseases." These constituted 8 per cent of the total).

Similar studies in New York State and in Minnesota show about 86 per cent for the former, 79 per cent for the latter due to infection. These figures are under rather than over the truth.

Many Occupations More Hazardous Than Mining

There are more than one hundred occupations more dangerous than coal mining. Window cleaning, operating farm machinery, carpentry, quarrying and excavating are some of the more familiar occupations in which the risk of death and injury is greater than in mining coal.

Nevada has passed a law (Ch. 172, Laws 1923) to enable counties to establish and maintain public hospitals, levy a tax and issue bonds therefor, elect hospital trustees, maintain a training school for nurses, and provide suitable means for the care of disabled persons.

A Hundred Cardiacs at Work

(Continued from Page 703)

is apt to make cardiacs more conscious of their physical condition. With juveniles, there seems more reason for having special classes. Without such classes it would be impossible to give the physical attention necessary. This problem of the education of the juvenile cardiac is too large a one to be touched on in this paper, however.

Fifty of these one hundred cardiacs were trained in schools and twenty different schools were used for them. Through utilizing such a variety of training centers it was made possible to give more approximately the work the trainees desired. Where there is one large school the tendency is to place all cardiacs there irrespective of their individual tastes.

Succeed Where Others Fail

Nevertheless, there are certain advantages in a large training center for the handicapped such as the Institute for Crippled and Disabled Men, in New York. The Institute trains only handicapped persons. Through contact with many men with similar disabilities, they begin to build up a technic of the best methods to use towards each special group. The Institute is a free school and it is in no way commercialized. Its chief object is the individual study of each handicapped trainee. Because of the intensive study given to each student, the Institute has often proven successful where other schools have failed.

A number of smaller schools were also quite successful in training cardiacs where the principal would give individual attention to them. A millinery school which has about ten students was found particularly for-

tunate in securing work for all the students trained there. This school simulated a small shop and the girls, as soon as they were able, worked on orders for the trade. Another good school was a barber school, where the

doing their placement work, and therefore exposed the cardiacs to the danger of being sent out to positions not suitable for them. The influence upon the civilian disabled of schools which specialize in training disabled soldiers often is not the best. The disabled adult, who is not receiving maintenance, often becomes dissatisfied in a training school where there are many soldiers receiving compensation.

Besides training in schools, the Bureau of Rehabilitation also

secured placement training for a number of cardiacs in shops or factories. Many cardiacs came to the Bureau without any means of supporting themselves while learning a new trade and it was necessary to secure work for them at once. An effort was made to get work for them where they would have a chance to learn and this was successful in some

cases. On the whole, however, the cardiac who has been quite ill usually needs an adjustment period before he can go back into industry, and the school more frequently bridges this gap than the job. Placement training was secured for twelve cardiacs as follows:

Industry	Number at Trade
Electrical assembly . . .	4
Machinist	2
Diamond setting	1
Celluloid optical frame trade	1
Toy painting	1
Chicken farming	1
Engraving	1
Mechanical dentistry . .	1

No scheme of rehabilitation is complete without some place where they can be tested out. It is not practicable, usually, to test out the working ability of a severe cardiac by putting him directly into industry. He frequently becomes ill and the employer, who may be previously prejudiced against taking cardiacs, is more reluctant than ever to take them in the future.

TABLE III.—TRAINING IN SCHOOL.

Occupation	Approximate Length of Course	Students Number of Trained
Stenography, typing and bookkeeping	6-10 months	12
Jewelry	3-6 months	8
Millinery	3-4 months (half days)	4
Flower and leather	2 years	1
Pocket book pasting	3-4 months	3
Celluloid engraving	3-4 weeks	4
Barber	2-3 months	2
Mechanical dentistry	6-7 months	2
Printing—press feeding	3-4 months	2
Switchboard operating	2-4 weeks	1
Shoe machine operating	2 years	2
Dressmaking	6 weeks	1
Crochet beading	2-3 weeks	2
Novelty work	2 years	2
Vulcanizing	2-3 months	1
Clothing operating	4 months	1
Watch repairing	1 year	1
Filing (clerical)	1 month	1

Young women, trained at millinery work.

The commercialized business schools were not always found to be good places for training cardiacs. Because of the large number of students, there was often little individual attention given. These schools also frequently have an inexperienced person

A famous Medical Product and its name

UNTIL 1869 there was no such substance in materia medica as Petroleum Jelly. For all compounding, animal or vegetable greases were used. These became rancid or deteriorated otherwise and brought impurities in contact with the human tissues.

In 1869 Robert A. Chesebrough discovered a process of manufacturing Petroleum Jelly without the aid of chemicals or acids. This process not only removed all the impurities of the crude petroleum, but avoided the presence of highly irritating residues.

Chesebrough called his product "VASELINE" Petroleum Jelly and it was immediately recognized as a wonderful addition to medical science.

His product has now become an article of world-wide repute.

All these years "Vaseline" Petroleum Jelly has remained without an equal for quality and purity.

It is unnecessary to remind those of the medical profession who know this bit of history that to assure obtaining the Chesebrough product the designation "Vaseline" should be used when prescribing petroleum jelly.

Promote Health Through Entertainment and Instruction

Almost everyone engaged in promoting health—whether of individuals or the public—can use the moving picture as a means of entertainment or instruction.

Many hospitals, sanitariums, public health officers, etc., are applying this powerful agent with marked success. They are entertaining convalescents, instructing mothers in the care of babies, rebuilding wounded soldiers, promoting "swat-the-fly" campaigns, and a dozen other things that might be enumerated.

A great deal of film adaptable to such work is now available. And with a projector like the Acme, guaranteeing pictures equal to theatrical standards, and at the same time easily portable, you can get the maximum use out of a film. The Acme exclusive gold glass shutter is another big advantage since it enables you to stop anywhere on a film and show a still picture with no danger whatever.

Have you made a careful study of the value of moving pictures for your own work? Let us talk it over with you. Our long experience with the uses others have made of films enables us to answer many questions that are doubtless in your mind. Use the coupon for your own convenience.

There is needed a subsidized workshop for cardiacs a shop not run for profit, but which gives employment to the handicapped cardiac while he is becoming readjusted to work. It is

ment bureau which will act in cooperation with heart specialists. Such a bureau must insist on the classification of all patients. The function of such a bureau will be to coordinate

Cardiac and crippled boys in training at the institute for crippled and disabled men.

not profitable to run a factory for those who can work two, four, or six hours a day and whose working capacity must be graded until they have reached the eight hour day, but such a shop is necessary if we are to make any scientific attack on this problem. It will be found that some cardiacs are too ill ever to go out into industry, and they could remain permanently in such a shop. Its primary purpose, however, should not be to shelter the unemployable, but to act as a scientific method of judging the potential earning capacity of every cardiac.

For years the cardiac has been one of the greatest burdens on organized charity. Where the breadwinner has been idle, charity has been forced to support the family because there has seemed no way of adjusting the cardiac to work. The economic gain to society in every cardiac rehabilitated would counterbalance any expense necessary in maintaining such a workshop.

The more one studies this problem of the placement of the cardiac the more one is impressed by its complexities. There are a few conclusions, however, which we can draw from even this brief study.

(1) It is possible for many cardiacs to work. In fact, they are usually better at work than when idle.

(2) To rehabilitate cardiacs successfully is not a simple matter. We need a specialized vocational advise-

ment bureau which will act in cooperation with heart specialists. Such a bureau must insist on the classification of all patients. The function of such a bureau will be to coordinate

(3) There must be flexibility in the methods of rehabilitation. Training should not be concentrated in one school, but an effort should be constantly made to experiment with new methods of training.

(4) Placement training is very useful, but is not always possible, unless the potential working ability of the cardiac has been first tested out in a subsidized workshop.

(5) Employers must be educated to the fact that cardiacs may be made useful workers, if they are not exceeding their physical strength and are employed at jobs in which they are as skilled as other workmen.

Certification of Fitness for Athletics

Columbus, O., is charged by Dr. Emery R. Hayhurst with expending only \$11,000 of its budget of nearly one hundred thousand a year charged to "a program of school health," to health work proper, the rest being allocated to physical education activities not properly correlated with medical inspection and disease prevention. The argument of Dr. Hayhurst is for the requirement of a certificate of health and fitness for all children who participate in athletics, or even in organized play.

Carbon Monoxid Hazard to Tobacco Users

The much mooted question of whether the carbon monoxid present in tobacco smoke constitutes a hazard to the smoker in confined indoor spaces has been the subject of study at the experiment station of the Bureau of Mines at Pittsburgh. Three men, puffing merrily away for three hours in a closed chamber whose dimensions were one thousand cubic feet, experience no difficulty that could be attributed to this cause, even when the air became so irritating to the eyes that goggles became necessary. The report adds, however, that smoking would increase the smoker's hazard if he were caught by carbon monoxid gas from such sources as occur in the mining industry.

The West Virginia Department of Health is making strenuous efforts to qualify for admission to the birth registration area.

Improvement in public drinking water supplies in West Virginia is given chief credit with the reduction in the typhoid fever death rate in the state 50 per cent in five years.

A conference will be held in October under the auspices of the American Engineering Standards Committee looking toward an amalgamation of the National Electrical Code, which deals with fire hazards, and the National Electrical Safety Code, which deals with personal hazards, into a single document.

The members of the committee arranging for the conference are David Van Schaack, Aetna Life Insurance Company; Cyril Ainsworth, Pennsylvania Department of Labor and Industry; F. O. Evertz, Ohio Inspection Bureau; F. M. Feiker, Society for Electrical Development; H. W. Forster, Independent Bureau, and S. J. Williams, National Safety Council.

The New York State Conference of Charities and Correction will meet November 13-15, 1923, in Rochester. There will be general sessions on the following subjects: Children, Delinquency, the Family, Industrial and Economic Problems, Mental Hygiene, and Specialized Education. Richard W. Wallace, of the State Board of Charities, Albany, N. Y., is Secretary of the Conference.

Oregon Cities to Provide School Dental Clinics

Designed primarily to permit the city of Portland to divert certain public school funds for dental purposes, the Oregon legislature of 1923 passed a measure which permits cities having a school attendance of 25,000 to finance or to assist in financing school dental clinics to those desiring the service. This measure is to be voluntary and not in any sense is it to be compulsory. Effort to put through similar provisions for the entire state was defeated prior to the passage of this bill.

Fashions in Self-Medication

Wellsworth Life, the official organ of the American Optical Company, proposes that employees shall at least have opportunity to become informed on the hygiene of the eye, declares in a recent issue against fashions in popular eye remedies, and observes that they change about once a year for better or worse. As far as eye remedies are concerned, just now it is boric acid. In preceding years it was salt and water. Earlier, rose water was in vogue. Dr. Quack's eye remedy, as he admits in the label, "strengthens weak eyes" and Dr. Bunk's famous eye drops at a dollar a bottle "if used regularly," will enable one to read without glasses, have both been used; "a flax seed will always remove a foreign body," or a little warm milk and an eye stone were highly prized.

"Strangely enough," says the journal, "two of the remedies are of value. Practically every eye wash which is on the market, no matter whether the price is 10c or a dollar for a small bottle, consists essentially of boric acid. Boric acid is of value, but why pay a dollar for an ounce of its solution, when the dollar would make a bathtub full of the same stuff?"

"Some inflamed eyes need eye drops — others need ointments. Others need to be bandaged and kept at rest. Others need small amounts of belladonna or other drugs to conserve the eyesight. The best is none too good for your eyes and they are too valuable for mechanics to tinker with. You can take your watch to a blacksmith if you wish, or your automobile to a locksmith, but when the light goes out of your windows you may have only yourself to blame. Better use the medical service which is free or see your family doctor. Don't take chances with your most valuable eyes."

The Hetch Hetchy Water Supply of San Francisco

*With Water, Water Everywhere, and Not a Drop to Drink, San Francisco Has Ever Had to Go Far Inland for Its Fresh Water Supply.
The Hetch Hetchy Project is an Engineering Triumph.*

BY M. M. O'SHAUGNESSY, CITY ENGINEER, SAN FRANCISCO, CALIF.

SAN FRANCISCO is situated at the apex of a peninsula, with salt water on the north, east and west sides. Accordingly, it has been necessary from the beginning of the city's growth to secure water supply from sources some distance away.

The Spring Valley Water Company, which owns the system now supplying the city with water, began in 1862 to furnish water from reservoirs on the peninsula south of the city. The system was later augmented by bringing water from Alameda Creek and its tributaries, east of the bay. The company now supplies an average of 36,300,000 gallons daily, of which sixteen million gallons is taken from the peninsula, and 20,300,000 gallons from across the bay. Work now in progress will within two years make available about twenty-four million gallons daily additional water.

It was early realized that the city would eventually outgrow the water sources of the adjacent country, including those on the other side of the bay. In the years 1900 to 1902 studies

a municipally owned water supply sufficient to meet the needs of the city far into the future. The result of these investigations was the selection of the upper Tuolumne River as the new source, with Hetch Hetchy Valley, Lake Eleanor, and Cherry Valley as the principal reservoir sites.

Hetch Hetchy Valley is in the Sierra Nevada, 145 miles east of San Francisco, at an elevation of 3,500 feet. The watershed tributary to the reservoirs named covers an area of 652 square miles. It contains no permanent habitations and only one summer camp of any consequence. A large proportion of the surface is bare granite. The hardness of water at Hetch Hetchy is less than 20 parts per million, as against 100 parts in San Francisco's present supply.

The Hetch Hetchy Reservoir. Water is beginning to collect behind O'Shaughnessy Dam.

and surveys were made of water sources over the entire central part of California, with the aim of securing

The aqueduct route from Hetch Hetchy to the city, after penetrating the westerly part of the Sierra

Hetch Hetchy aqueduct. Delivering steel pipe at Red Mountain bar siphon.

Nevada, crosses the San Joaquin Valley, then passes through a second range of mountains (the Coast Range), then underneath San Francisco bay, and finally into the city by way of the peninsula; a distance along the line laid down for the aqueduct of 168 miles.

Water is to be delivered to the city by gravity through an aqueduct whose ultimate capacity is to be four hundred million gallons per day. Water is to be conveyed through the mountain ranges in tunnels, and across both valleys in closed steel pipes.

The drop in elevation between Hetch Hetchy

and San Francisco is sufficient to carry the water the entire distance by gravity, and leave a surplus head of 2,500 feet, which will be used to operate a series of hydro-electric power stations. Storage is provided for at the upper end of the aqueduct by Hetch Hetchy and Lake Eleanor reservoirs, and near the point of delivery by connection to the reservoir of the Spring Valley Water Company on the peninsula.

Bonds were voted in 1910 to finance the Hetch Hetchy work, but construction was not begun until the right to make use of public lands was obtained from the Government. In 1913 Congress passed an act granting to the City of San Francisco the right to construct, operate and maintain the dams, aqueducts, power plants, roads, trails, etc., which are a part of its water supply and power system in the

reservoirs, respect certain prior irrigation rights, and pay a graduated tax

Pouring concrete at night into O'Shaughnessy Dam. The lights and spouting system were suspended from cables anchored to the sides of the canyon.

up to a maximum of \$30,000 annually.

On the part of the Government, the act provides the following sanitary regulations to protect the reservoirs and their tributary streams against pollution:

(a) That upon the completion of the Hetch Hetchy Dam or the Lake Eleanor Dam, in the Yosemite National Park, by the grantee, as herein specified, and upon the commencement of the use of any reservoirs there-

Yosemite National Park, in the adjacent Stanislaus National Forest, and in other public lands.

The city is required under the act to prosecute the construction work without lengthy interruptions. The city must make its permanent structures of a slightly design, must observe precautions against fire and other minor regu-

by created by said grantee as a source of water supply for said grantee, the following sanitary regulations shall be made effective within the watershed above and around said reservoir sites so used by said grantee:

First. No human excrement, garbage, or other refuse shall be placed in the waters of any reservoir or stream or within three hundred feet thereof.

Second. All sewage from permanent camps and hotels within the watershed shall be filtered by natural percolation through porous earth or otherwise adequately purified or destroyed.

Third. No person shall bathe, wash clothes or cooking utensils, or water stock in, or in any way pollute, the water within the limits of the Hetch Hetchy Reservoir or any reservoir constructed by the said grantee under

the provisions of this grant, or in the streams leading thereto, within one mile of said reservoir; or, with reference to the Hetch Hetchy Reservoir, in the waters from the reservoir or waters entering the river between it and the "Early intake" of the aqueduct, pending the completion of the aqueduct between "Early intake" and the Hetch Hetchy Dam site.

Fourth. The cost of the inspection necessary to secure compliance with the sanitary regulations made a part of these conditions, which inspection shall be under the direction of the Secretary of the Interior, shall

Hetch Hetchy aqueduct. Mountain Division tunnel with lining partly completed.

be defrayed by the said grantee.

Fifth. If at any time the sanitary regulations provided for herein shall be deemed by said grantee insufficient to protect the purity of the water supply, then the said grantee shall install a filtration plant or provide other means to guard the purity of the water. No other sanitary rules or restrictions shall be demanded by or granted to the said grantee as to the use of the watershed by campers, tourists, or the occupants of hotels and cottages.

These regulations will affect only a few summer camps and such private camping parties as will visit the locality. There are no industries upon the watershed, and the greater part of it is uninhabited.

The aqueduct will consist almost entirely of tunnel and pipe, so no sanitary problems arise in the lower divisions of the system.

The city began construction in 1914. The first unit of construction was the Hetch Hetchy Railroad, extending sixty-eight miles from Hetch Hetchy Junction to the site of O'Shaughnessy Dam, following generally the line of the aqueduct. A temporary hydro-

electric power plant was built, taking water from Cherry Creek and generating about 3,000 KW. for use on dam construction, tunneling operations, etc.

Lake Eleanor, the first unit of the storage system, was completed in 1918. It is a buttressed arch dam 1,260 feet along the crest and seventy feet high above stream bed. It raises the level of Lake Eleanor (a natural lake before the construction of the dam) and makes available a storage of about nine billion gallons. Upon its construction, the dam was immediately put to use to regulate the flow of the Cherry River, from which water to operate the construction power plant is diverted.

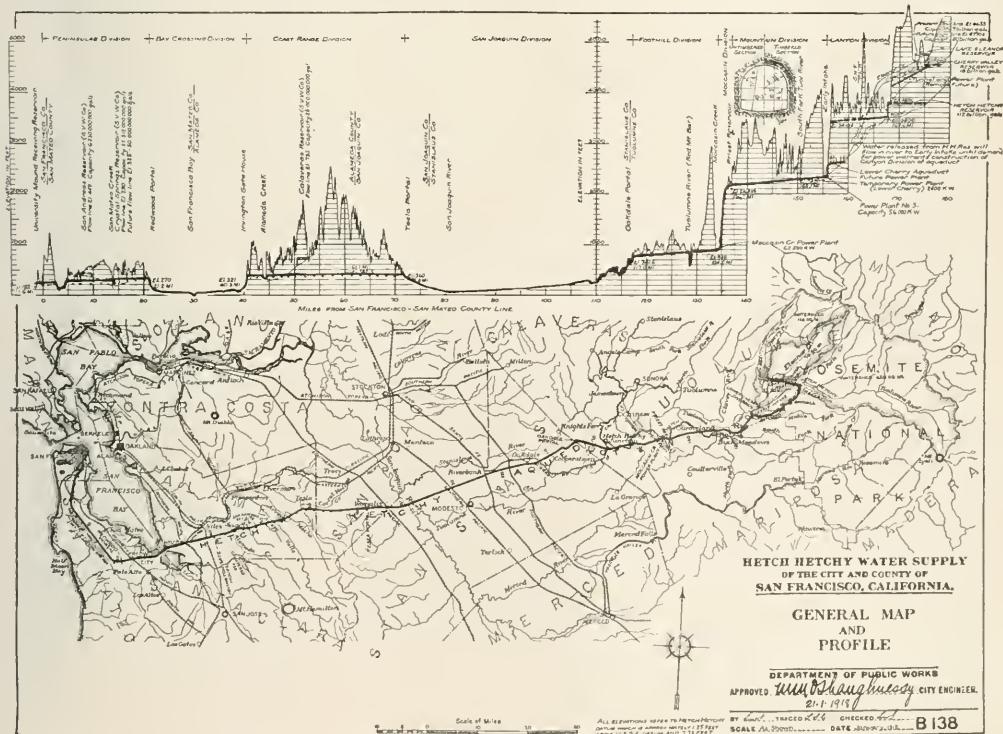

The dam at Hetch Hetchy, on the Tuolumne River, was completed in February of the present year. The dam is of the gravity type, built of cyclopean masonry. It is 114 feet deep in foundation below stream bed and 226 feet high from the steam bed to crest, and 600 feet long at the crest. It impounds water from a watershed of 459 square miles, the capacity being sixty-seven billion gallons. It was built by the Utah Con-

struction Company at a contract price of about six million dollars.

The stream from Lake Eleanor and from Hetch Hetchy Reservoir run together twelve miles below the latter. Near this point is the intake of an 18-mile tunnel which forms the upper or Mountain division of the aqueduct. Over 95 per cent of this tunnel has been excavated. The greater part of the tunnel will be lined with concrete, to an inside area of eighty-eight square feet. The slope of the tunnel is slightly greater than the hydraulic grade, so that the tunnel will flow full. The capacity is four hundred million gallons per day.

Water will be discharged from the Mountain Division tunnel into a forebay reservoir, and thence supplied to the Moccasin Creek Power Plant, which is now under construction. Ninety-three thousand horsepower generating capacity is being installed, with provision for future addition of 46,000 horsepower more. The 24-hour average power capacity (determined by the amount of water available) will be seventy thousand horse-power.

Right of way is being purchased for aqueduct—(Continued on Page 834)

Physical Condition of Jewish Children in Poland

Nutritional Factors Here Cannot Be Dissociated From Hygienic Factors. Practically All of the Rachitic Children Were Likewise the Victims of Bad Housing

BY SAMUEL NEWMAN, M.D., LATE MEMBER MEDICAL COMMISSION, AMERICAN JOINT DISTRIBUTION COMMITTEE, VOLUNTEER PHYSICIAN, CHILDREN'S CLINIC, UNIVERSITY OF VIENNA, VIENNA, AUSTRIA.

BY the end of 1920, the American Joint Distribution Committee considered conditions in Poland sufficiently stabilized to plan a program of constructive medico-sanitary work among the three million Jews living in that country. In January, 1921, a medical commission was sent over to Poland, under the leadership of Dr. Harry Plotz, to study and report upon the medico-sanitary situation in Poland, particularly with a view of outlining a program of medical reconstruction of Polish Jewry.

It was to be expected, *a priori*, that the war and post-war conditions in eastern and central Europe had a greater deteriorating effect upon the health of the Jewish masses than upon the non-Jewish. This presumption was based upon the following considerations:

(A) Jews, being chiefly city dwellers, were subjected to a greater degree to the ill effects of the bad housing conditions prevailing all over Europe as a consequence of the war.

(B) The urban classes of population suffered more from food shortage than the rural classes.

(C) Hundreds of thousands of Jews were expelled from the Western war areas by the Russian military authorities and were driven into the interior of Russia. This procedure brought economic ruin to a great proportion of the Jewish population and caused the dissemination of epidemic diseases among them.

(D) The Bolshevik invasion of Poland caused a great influx of refugees from the Eastern regions into the interior cities, thus aggravating the bad housing conditions and spreading also epidemic diseases.

The studies of the Medical Commission support the presumption that the war had a particularly telling effect on the health of the Jews in Europe. This paper, however, is limited to a study of the physical condition of Jewish children only, particularly of the poor classes. To the student

of health problems in Poland, special studies of the health conditions of the Jews of that country are also important, as they constitute 14 per cent of the total population of Poland. In Table I are the records of the physical examination of 6,308 war orphans, who were gathered in by the American Joint Distribution Committee for support and care.

Analysis of Table I

In the examination of this group of children uniform examination blanks were used, but the local physicians—who actually did the examining—did not carry out the work in accordance with a uniform, rigid objective standard, such as would be required for reliable statistical data. However, all the errors were on the side of conservatism and omission. The data that has been supplied by the local examiners has been resifted and classified in a way to give the least possible error.

Under malnutrition—admittedly a vague clinical entity—were classed all cases with the diagnosis of undersized, light weight, very anemic, and starved. It is to be regretted that no uniform height-and-weight table, or any of the well tried out nutrition indexes, were used in these examinations. Yet, it is the author's impression that had any nutrition index been used, the number of cases classed under malnutrition would have been even still higher. The Polish physician, working amidst starvation and disease, naturally would be inclined to place the standard of the normal below the point we would consider it to be. Further, observation justifies this opinion. In the examination of school children in Lodz in accordance with the Camerer scale, the local examiners did not class a child as undernourished if its height was above that for its age and its weight below that for its height. In other words, a child was considered undernourished only when its height did not exceed

that indicated on the scale for its age, and its weight was appreciably below that indicated for its height.

Dental caries, was probably correctly recorded. A diagnosis of pulmonary tuberculosis was discarded. A diagnosis of pulmonary tuberculosis below the age of puberty falls within the field of the trained pediatricist who must also resort to the Roentgen rays and tuberculin test as diagnostic aids. All conditions of the lungs have been grouped under one heading, as diseases of the lungs.

Under lymphadenitis are grouped cases diagnosed as cervical adenitis, tuberculous glands of the neck, and adenitis. The inquiry on the examination blanks was after active cases of, and signs of past, suppurating glands in the cervical region. There is no doubt that the majority of cases under the heading, lymphadenitis, represent adenitis tuberculosa.

In the cases diagnosed as rachitis it simply means a rachitic bony deformity. Among these children there were very few infants, and there can be no question of the finer Roentgen and blood-chemical methods having been used in the diagnosis of this condition. A diagnosis of ricket in Poland beyond the nursing age simply means a marked rachitic deformity: It is cases similar to Fig. 1 that are called rickets in Poland.

In the differential diagnosis of favus, many other diseases of the scalp come into consideration, such as psoriasis, seborrhea, eczema, impetigo, lupus erythematosus, and herpes tonsurans. Polish physicians are familiar with favus and it is correctly diagnosed by them. The same is also true of trachoma. However, I am of the opinion that many cases classed under, chronic conjunctivitis, were really conjunctivitis phlyctenulosa, a tuberculous manifestation in the mucous membrane of the eye.

Analysis of Table II

Table II presents the records of the

physical examination of 19,543 children of the poorer classes in the Brest-Litowsk, Ukrainian, and Bialystok districts, or the Eastern provinces of Poland. These examinations were conducted by local physicians under the management of Doctors Wendkos, Golub, and Friedman, members of the Medical Commission.

With the exception of one thousand war orphans and 274 refugees from Russia, all these children are of the poorer classes. Even though these examinations were directed by members of the Medical Commission, yet no complete returns were sent in. However, the data of this group is more reliable and represents a nearer approximation to the true physical condition of Jewish children in Poland. The total disease percentage in this table is 75.5 as against that of Table I, which is 61.3.

The percentage of malnutrition in this group of children is nearly twice as high as in the previous group. Dental caries were noticed in nearly similar proportion in both groups of children. Under diseases of the lungs endeavor has been made to list only chronic conditions, in order to obtain an idea as to the prevalence of tuberculosis. We therefore see that while Table I. shows under diseases of the lungs a percentage of 8.5, Table II. shows only a percentage of 2.25, having eliminated as much as possible non-tuberculous conditions.

Concerning the small percentage of heart lesions listed in Table II., it may be said that from other studies on the frequency of heart lesions

among the children in Poland, Dr. Wendkos entertains the opinion that heart lesions resulting from rheumatic fever are far less common in Poland than in the United States. Dr. Wendkos tries to explain this by the lesser occurrence of oral sepsis among the

districts of Poland as compared with the interior regions. The local physicians did not enter into the finer points of the diagnosis of tuberculous lesions of the joints, but have simply listed the more evident forms. It was not unusual at all to find among school

children advanced cases of tubercular disease as that presented in Figure 2.

Table III presents several studies in the health condition of Jewish children in Congress, Poland, a section which fared better during the war than other sections of Poland. These studies concerned themselves mainly with the question of tuberculosis. Uniform methods of examination were carried through by the author, assuring himself of uniformity by making the examinations himself. Roentgen and laboratory methods of diagnosis, as well as cooperation of specialists, were resorted to when it became necessary to clear up a doubtful point.

The physical examination of 1,810 children in Congress, Poland, included 530 war orphans and

1,280 school children of the poor social strata. The examination was limited to a few diseases.

Analysis of Table III

In the group listed as affected by *Adenitis tuberculosa*, both active and healed cases were included. In the examination for evidence of past and present adenitis tuberculosa all other conditions were kept in mind which might cause an adenitis, particularly of a chronic type, such as malnutrition, rachitis, and lymphogranu-

Total	3,185	1,997	63.

children in Poland, particularly the *Streptococcus viridans*, as compared with its occurrence in the United States. However, no extensive bacteriological work has been done in Poland to clear this point.

Favus is listed in Table II. as occurring in the same percentage as in Table I. Tuberculosis of joints also reported in Table II. From personal observation the author has been led to believe in the greater occurrence of tuberculosis of the joints among the children of the eastern dis-

loma. The disfiguration caused by the cicatrization of the tubercular glands in the cervical region was at times very depressing.

In listing children in the malnutrition group only such cases were selected which could not show an immediate cause for the undernourishment. In other words, an attempt has been made to establish malnutrition as a clinical entity. It must be admitted that such a procedure is highly artificial, for it may be argued rightly that malnourished children form a class from which those with manifest tuberculous lesions are recruited. Yet in Poland it was found expedient to designate a clear-cut group of children as malnourished and to subdivide them into different grades in order to know which children to admit to certain social relief benefits, such as kitchens, summer colonies, etc.

In designating a child as malnourished the *Sacratama* method of Pirquet¹ was used. This method, as it is well known, estimates the four main qualities of the condition of nutrition; namely, *Sanguis*, the blood content of the skin; *Crassitudo*, the subcutaneous fat; *Turgor*, the water content of the subcutaneous tissue; and *Muscularis*, the strength and quality of the musculature. Each of these four qualities is graded thus: (i) very much above normal; (e) above normal; (a) normal; (o) subnormal; (u) very much below normal.

A child with a pale skin and muscosa, with diminished subcutaneous

fat, with normal turgor, and flabby muscles, would receive a rating of *sacratama*.

Diagnosis in Young Subjects

The examination for this rachitis is a highly subjective matter and in the hands of different examiners will

Chart I.—An idea of the incidence of tuberculous infection was sought through the tuberculin reaction with the above results. The rate of infection increases with the age of the child.

yield varying results. In the examination of very young children no examination is satisfactory unless Roentgen rays and chemical blood analysis are made use of. In this series of examinations there were very few children under two years of age and therefore no florid cases were noticed. All cases noted were healed and only manifested themselves through bony deformities ranging from only the rachitis rosary to severe cases of scoliosis.

The percentage of favus is strikingly similar in all the three groups of examinations, ranging from 3.23 per cent as the lower figure in Table II. to 4.08 per cent in the last group of children.

In the 27 cases of pulmonary tuberculosis found in the last series of examinations, 13 cases were corroborated also by Roentgen diagnosis. These cases ranged between 9 and 14 years of age, 7 occurring at 14; 8 at 13, 4 at 12; 4 at 11; 2 at 10; and 2 at 9.

An attempt was made to obtain an idea of the incidence of tuberculosis infection among Jewish children in Poland by means of the tuberculin

skin reaction. This method, because of its simplicity and the readiness with which results can be interpreted, was found very useful in Poland. In order to obtain uniform results the same stock of old tuberculin, Koch, was used.

Evaluation of Data

In evaluating the data in all the foregoing tables we note a very high rate of disease among Jewish children in Poland. The greatest number of disease may be said to have been caused by malnutrition—meaning here simply the lack of nourishing food. Tuberculosis in children may be rightly termed a disease of malnutrition. While not intending here to enter into a discussion of the etiology of rickets, the author wishes to say that in Poland it was found impossible to dissociate the nutritional factor from the hygienic factor. Those classes of the population which suffered most during the war from lack of food were practically also those subjected to bad housing conditions. The high incidence of favus among Jewish children in Poland, as noticed by all the members of the Commission, may also be due to the bad housing conditions. Only several months ago all the Jewish community buildings in the Eastern border regions of Poland were congested with reimmigrants from Russia.

This study suffered from the fact that no pre-war data on the physical condition of Jewish children is here presented. Unfortunately no such data could—(Continued on page 896)

A Fresh Air Camp for Under-nourished Children

The Sun Cure, Often Employed for the Treatment of Tuberculous Children, Is Here Effectively Used With the Pre-Tuberculous

By DONALD D. SHIRA, A.B., M.D., DIRECTOR OF HEALTH; AND ELIZABETH J. YOST, R.N., DIRECTOR OF NURSES, AKRON, OHIO.

IN every community there are proportionately a large number of undernourished children who present a serious problem to official and voluntary health agencies. The importance of the proper care and supervision of these children, especially in reference to a carefully planned anti-tuberculosis program, can scarcely be overemphasized. Often found in homes of actual want with the usual concomitants, ignorance and insanitary surroundings, many of them in direct contact with active cases of pulmonary tuberculosis, these children offer most fertile soil for the spread of this dread disease. For these unfortunates society provides no place of refuge until they have actually contracted the disease, when the doors of hospitals and sanitoriums are thrown open to them.

Why wait until that happens? Why not take, in time, whatever measures are necessary to prevent such tragedies and to insure to these children a life of usefulness free from physical suffering and mental anguish?

In an endeavor to meet this situation in Akron, Camp Christmas Seal was established. Financed by the sale of Christmas seals it was sponsored by the Federation of Women's Clubs and was under the direct supervision of the health department. This article is written for the sole purpose of giving the benefit of our experience to others who might be contemplating establishing a similar camp.

Having decided to establish a camp, the first consideration is the selection of a site. This should be done very carefully. There should be plenty of fresh air, with protection against heavy winds; it should have both shaded and sun-lit areas, abundance of pure water for drinking and bathing purposes, and means for proper disposal of sewage.

For Camp Christmas Seal an uncultivated fruit farm belonging to the city of Akron and overlooking a beautiful inland lake, was secured. There are a commodious farm house and an ex-

ceptionally large barn on the premises. Both house and barn were screened, the house serving as kitchen, dining room, and dormitory for the girls and female attendants, the barn as a dormitory for the boys and a playground in inclement weather.

Selection of Children

Akron is fortunate in having under way a comprehensive anti-tuberculosis program. The work is well organized under the Springfield Lake

"London Bridge is Falling Down."

Sanatorium and the Akron Health Department—a modern sanatorium, open window rooms, tuberculosis clinics, school physicians and special tuberculosis nurses. Through these sources it was very easy to apprehend a large number of children eligible for such a camp.

Some two hundred children were recommended, but since the camp could accommodate only twenty-four it became necessary to exercise minute care in making the selections. Dr. Clarence Hyde, superintendent of Springfield Lake Sanatorium, made a thorough physical examination on each of the two hundred children. The decision as to the eligibility for ad-

mission was based upon age (six to twelve years inclusive), the height-weight index, the general physical condition, absence of any infectious or contagious disease, the home conditions, and the family history. Diagnosed cases of pulmonary tuberculosis were not accepted.

It might, by way of suggestion, be well to mention the advisability of including a mental test in the examination. One mentally deficient child in a camp of this nature may exert a very deleterious influence upon the general morale, and it is highly essential that firm discipline be preserved at all times.

It was required that each child admitted to the camp present a consent slip, signed either by the parent or guardian, relieving those conducting the camp of any responsibility in case of accident, illness, or loss of property.

Group accident insurance was carried on the children at the camp.

The consent slip reads as follows:

Camp Christmas Seal Conditions

The object of the *Fresh Air Camp* is *Better Health*. Children will be under the supervision of a physician: Nurses will be on duty night and day. There will be a man and wife as caretakers and a professional cook to prepare and serve the meals. Children will build strong healthy minds and bodies and be able to enter school ready to cope with the year's work. Camp is limited to 24 children.

The parent or guardian accepting this favor from the Health Department and Federation of Women's Clubs, assumes all risk of accidents and expressly agrees that the Health Department and Federation of Women's Clubs shall not be liable under any circumstances whether by negligence of its agents or otherwise, for an injury to the person, or for any loss or injury to the property of the person accepting this favor. The Health Department will do all in its power to protect the life and property of the children accepting this favor.

I accept the foregoing conditions.

Parent
Guardian
Name of Child.....

Attendants

Three Health Department nurses were on duty constantly. It is not well to change the nursing personnel during the course of the camp. After the children become acquainted with nurses who have learned their peculiarities and idiosyncrasies, to substitute strangers disturbs the

Children did not seek a shady spot, but a place in the sun for story hour at this fresh air camp, where the sun plays an important part in camp life. Children at the camp wore no clothes other than trunks during sun-cure periods. Sun cure was supervised by Dr. C. L. Hyde, superintendent of the tuberculosis hospital, who saw to it that the protective coat of tan was acquired gradually.

camp equilibrium and favors the lowering of the disciplinary standards.

For the general care of the camp and the cooking, two women and one man were employed, the other two, man and wife, twenty-five dollars per week, keep included for all.

Health department physicians made regular visits to the camp.

These of course are variable, depending entirely upon the character and setting of the camp and the number of children to be cared for. In this case the local Red Cross Chapter loaned cots, mattresses, pillows and furniture. Each child was supplied with one double cotton and one heavy woolen blanket. Each child had his own wearing apparel as well as personal articles.

Boy's Camp Outfit

- 3 pairs pajamas or 3 nightgowns.
- 1 pair shoes.
- 3 pairs stockings.
- 4 pairs washable pants.
- 6 waists.
- 1 sweater or coat.
- 1 hair brush or comb.
- 1 tooth brush.
- 6 handkerchiefs.
- 3 suits underwear if necessary.

Girl's Camp Outfit

- 3 nightgowns.
- 1 pair shoes.
- 3 pairs stockings.
- 4 dresses.
- 3 pairs bloomers or underwear.
- 1 hair brush and comb.
- 1 toothbrush.
- 6 handkerchiefs.

Food:—No attempt was made to force-feed the children. A great variety of wholesome, substantial food was served—plenty of milk, eggs,

vegetables, fruit, bread and butter and some meat.

Daily Schedules:—A daily schedule was adhered to as strictly as circum-

Blowing bubbles, one of the favorite pastimes of children at the fresh air camp.

stances would permit. Visiting hours were limited to Sunday afternoon. The schedule, adopted after much careful thought follows:

Camp Christmas Seal Schedule

Rise	6:30 a. m.
Breakfast	7:00 a. m.
Sun Cure	8:00-9:30 a. m.
Bath—Showers	9:30-10:00 a. m.
Rest Cure	10:00-11:00 a. m.
Play—get ready for dinner	11:00-12:00 a. m.
Dinner	12:30 p. m.
Rest	1:30-3:00 p. m.
Sun Cure	3:00-4:30 a. m.
Showers	4:30-5:00 p. m.
Play	5:00-6:00 p. m.
Supper	6:00 p. m.
Play	6:30-8:00 p. m.
Bed	8:00 p. m.

Of course the length of time devoted to the sun cure and rest varied, the sun cure period being gradually lengthened and the rest period shortened until the two were equalized to conform to the schedule as indicated. This was supervised by Dr. Hyde who has had a great deal of experience with the sun cure in the treatment of tuberculosis. During the sun cure loin cloths only were worn thus exposing the entire body surface to the sun's rays.

RESULTS: The results obtained were extremely gratifying. The improvement possible in the physical condition of such children in the short period of six weeks is remarkable. The change in their appearance became apparent to the most superficial observers. Pale faces became ruddy, wistful looks were replaced by those of happiness, flabby muscles became firm and rounded out, and the posture improved.

Very accurate records were kept, pulse, respiration, temperature and weight being checked up twice each week. The—(Continued on page 836)

These little warriors fight for good health at Camp Christmas Seal while playing Robin Hood. Heliotherapy (sun cure) which is being successfully used in children at the Springfield Lake Tuberculosis Hospital, at Akron, O., was also used at the Fresh Air Camp, maintained during the summer months by the Akron Health Department and the Federation of Women's Clubs.

Cardiac Clinic of the Michael Reese Dispensary

Definitely Organized to Meet the Needs of Patients with Cardiac Handicap Who Require Prolonged Supervision As Well As Social Adjustment

By ELEANOR DODGE, SOCIAL WORKER, CARDIAC CLINIC OF THE MICHAEL REESE DISPENSARY, CHICAGO, ILLINOIS.

THE Cardiac Clinic of the Michael Reese Dispensary is one of twelve refer clinics, drawing its patients primarily from the general medical and pediatrics departments. The only exception to this method of admission to the special clinic is that hospital patients may be referred directly to the specialized department from the Michael Reese Hospital of which this dispensary is the out-patient department. These patients referred from the hospital are interviewed in the Dispensary admitting room just as are all other patients who are new to this institution. Ten per cent of all individuals applying for dispensary care are not accepted as patients because they are found to be financially ineligible for this service. They are referred to the private offices of physicians serving on the staff of the dispensary. The worker in the admitting room, a member the social service department, in accordance with the general policy of the dispensary, is particularly lenient with those patients coming directly from the hospital with definite cardiac diagnoses or other significant conditions which necessarily mean prolonged medical treatment and supervision as well as frequent social adjustment.

The Cardiac Clinic meets weekly on Saturday mornings. Though the clinic is a unit, it is divided into a children's and an adult service. Each of these services has its own staff and quarters. The physicians serving the adult group are drawn from the general medical department of the Dispensary and those serving the children from the pediatric department. At the present time there are on the staff: 2 physicians in children's cardiac clinic; 3 physicians in adult cardiac clinic; 1 clinic secretary; 1

nurse, and 1 social worker who serves both groups of patients.

The clinic secretary, who is a volunteer, admits each patient to the clinic, recording in the day book name, address and floor on which patient lives. Later she records on the individual medical records the patient's temperature, pulse and weight—which have been ascertained by the clinic nurse—and sees that the doctors re-

details as the patient's participation or non-participation in gymnasium work or other group exercises is also noted. This detailed information is kept by the worker in a card file for her own use but which is at any time accessible to the physicians. A summary of the salient points obtained, however, is at once transcribed to the patient's medical record.

The medical record used in the children's cardiac clinic is a form based on that developed by Dr. William St. Lawrence of New York. In the adult clinic the physicians have previously used blank sheets making their own notations. After careful study of the charts used in several other cardiac clinics, a new form has recently been developed. As each patient is accepted in this clinic, complete laboratory tests, including x-ray and electrocardiograph are recommended. With these reports plus clinical findings, the doctors are now grouping the children according to their degree of exercise tolerance. It is our aim to have classes providing graduated exercises for these groups.

Outside the clinic the activity of the social worker divides itself into three phases. These are the steering problem, case work with patients referred by physicians in the clinic, and the medical follow up problem. The so-called steering problem includes the group of patients under observation and treatment in the cardiac clinic who are also known to other social agencies. When these other agencies are carrying the major responsibility of the patient, the medical social worker gives information and instruction to the patient in the clinic only, as she has no contact with him in his home. Supplementary instruction and reports, however, are

Physician examining patient in the Children's Cardiac Clinic.

ceive these charts. She makes laboratory appointments and takes charge of clerical routine connected with the clinic. She also takes the previous medical history of new patients, as time permits before the arrival of the physicians in clinic.

All Cases Investigated

The social worker interviews each new patient reporting to the clinic for the first time. In this interview, she seeks to learn the family group with the general health of each member, the home situation including financial, living, and sleeping conditions, recreation, employment or school activities with the physical environment involved in each. In the school activities of the children, such

also given by correspondence to the other agencies interested and they in turn, keep us informed of the results of their social activity. It may be added that though this is our general policy, whenever emergencies arise, the medical social worker has access to any patient's home and is free to make any temporary arrangements which would be of benefit to the individual patient.

The case work with individual patients not known to other agencies is similar to medical social case work with any other group. It involves, of course, visiting in the homes to insure the carrying out of the physician's recommendations in relation to living conditions, limitation of responsibilities, convalescent care, change of occupation, vocational training or occupational work within the home, according to the individual problem. In the case of children, there is the problem of adjusting the living conditions to meet the requirements of limitation of exercise, the education of the mothers as to their responsibilities, recreational supervision and special school arrangements. These school adjustments include special arrangements in the public schools, the principals being very cooperative in excusing children from strenuous gymnastic exercises and in allowing them privileges in climbing and descending the stairs at their leisure. The individual grade teachers have also been interested in personally supervising the school lunches for cardiac children. Some of the schools have introduced facilities for serving a glass of milk or a bowl of soup with crackers to the children during the morning session. This provision has had a marked effect on many of the cardiac and malnourished children. The public school system of Chicago also includes three schools with facilities for caring for crippled children. A small number of the more seriously handicapped cardiacs have been admitted to these institutions. The Board of Education furnishes a "bus" to transport these children to and from school. While attending schools of this kind the children have definite rest periods during school hours and have their luncheons served at school. Furthermore they indulge in whatever exercise is allowed them under

the closest medical supervision. The school authorities, through the medium of the social worker in the clinic, are constantly in touch with the physician interested in the given child, gradually allowing more and more freedom until he is again able to return to the regular public school classes with the minor restrictions available there. The following is an example showing the value of such special provisions for cardiac children:

Sam A., a child of 10 years, was referred from the Michael Reese Hospital to Michael Reese Dispensary Cardiac Clinic in August, 1921 for medical supervision following a two month period of hospitalization. The diagnosis was pericarditis with effusion. Investigation by the social worker revealed a family of six children, ranging in age from 10 years to

Social worker taking first interview with referred patient.

22 years. This family lived in a six room flat in an uncrowded neighborhood. The rooms were of medium size, light and airy. The mother was unusually intelligent and cooperative in her care of the boy. Admission to one of the special schools mentioned above was secured for Sam. He reported regularly to the cardiac clinic throughout the school year. In July, 1922, he was given a six week's outing at a cardiac camp. In addition to the vacation in the open country which this afforded, Sam also had the benefit of restricted exercise as advised by his own physician through the cooperation of the camp authorities. When he returned to clinic following this summer outing, his condition was markedly improved. In September, 1922, he returned to the special school and continued his periodic visits to the cardiac clinic. Improvement was noted chiefly in that his temperature and pulse rate were decidedly lower and his general condition was apparently normal over a longer consecutive period than previously. By December, 1922, his condition was sufficiently improved to warrant the tonsillectomy he had long

needed. Arrangements were made for this operation at Michael Reese Hospital where the child could remain as long as necessary following the operation. At the end of January, 1923, the physician advised that Sam could be discharged from the special school to the regular public school with limited exercises. This transfer was made and to date the patient has made good progress.

Training the Handicapped

In planning for vocational training for the older children and for the handicapped young people the Scholarship Association, the Board of Education and the State Rehabilitation Commission have proved helpful resources. The Scholarship Association provides scholarships for Jewish children over fourteen years of age who cannot otherwise continue in school. They are usually awarded to children who are physically handicapped or who give promise of special ability, both of which conditions suggest the advisability of further training. This scholarship in addition to allowing the child his school supplies and other incidental expenses, pays the family a sum which approximates the wages of the child were he at work. The Vocational Guidance Department of the Board of Education is particularly helpful in advising the young boys and girls who are leaving school or who seek part time employment outside of school

hours as to openings compatible with their physical endurance. In January, 1923, this Bureau opened a department for the particular study and placement in industry of young girls suffering from definite cardiac difficulty. The state rehabilitation commission has a state and federal fund which is entirely for the use of the re-education of physically handicapped individuals who are amenable to some form of training. Through this fund a seventeen year old boy with a severe cardiac lesion has recently been provided with a complete outfit of tools preliminary to training and apprenticeship in watch repair work. In addition, the tuition necessary for this patient's instruction was supplied from the same fund.

As to occupational work for the smaller children at home, some of them have continued with the reed basketry—(Continued on page 838)

The Detection and Prevention of Typhoid Epidemics*

Slow to Develop, Difficult to Detect, B. Typhosis Still Takes its Toll. Successful Prevention Achieved Through Sanitary Safeguard Rather than Artificial Immunity.

By J. FREDERICK JACKSON, DIRECTOR, BUREAU OF SANITARY ENGINEERING, DEPARTMENT OF HEALTH, HARTFORD, CONN.

MANY years ago, "a sneaking, vicious, elusive criminal made his appearance in the world and for a long time poisoned many people, causing untold suffering and sickness and many deaths. So sinister and various were his methods of attack that it was a long time before suspicion was directed to him, and many wearisome years of misdirected investigation elapsed before he was definitely identified as the author of outbreaks and epidemics devastating in extent, but previously attributed to unpreventable bodily ills to which the human race was naturally liable.

He was most insidious in selecting and approaching his victims, and because the effect of his attack was slow in developing, when an investigation was started detection was very difficult, most of the evidence having disappeared or having been destroyed.

His operations finally became so widespread and his attacks so bold and deadly that systematic efforts were made to protect his victims.

These soon developed some interesting facts, one of which was that he was harmless unless he could establish himself within the body of his victim. This he generally sought to do by concealing himself in such a manner or in such media that his presence was entirely unsuspected, making him unconsciously assist in his own destruction. A favorite way was to conceal himself in the food

or drink, or in matter which none too clean persons touched with their hands. Sometimes when other means failed, he made use of insects to reach the food and drink of his victims.

Difficulty of identification and lapse of time before the effects of his presence were felt made his method of attack hard to predict. It was also difficult to secure any reliable traces once he had been successful in reach-

ing a victim. The evidence for prosecution and conviction in most cases was lamentably weak, and society for self protection had to adopt general safeguards. This notorious criminal is the typhoid germ *B. typhosus* and its unchecked career was unquestionably due to lack of care in disposing of the wastes from the human body.

The methods of general protection at first tried were to prevent drinking water and shellfish from becoming contaminated, afterwards they were extended to protecting milk and other food products. The effect of these efforts was a marked decrease in the typhoid rate and the campaign was further extended to making contaminated water, milk, and other food products safe by filtration, sterilization or by pasteurization. Efforts were also made to develop immunity within the body of the victims by the general application of anti-typhoid inoculation. As a result, the progress in these fields has been most marked and the consequent drop in morbidity and mortality rates from this scourge most gratifying. It must be admitted, however, that the advance in detecting and eliminating the particular source from which epidemics arise has not kept pace with other preventive measures. Since the end sought is the positive stamping out of this disease and since this result will be more quickly obtained if efforts are directed at the source and before it has gotten a foothold, a review of the more important outbreaks in Connecticut so far as the records

are available is of interest. The four charts making up this epidemiological study have been abstracted from the reports of the State Department of Health from 1880 to 1918. They are grouped chronologically, giving the location, number, medium of infection, and the source where it was definitely determined. The distribution by counties and towns is not very informative. New Haven in New Haven County, and Middletown in Middlesex, appear to have suffered most, and outbreaks in general are along the coast and large rivers. Very little significance can

Spot map of Connecticut showing where occurred the epidemics studied. Outbreaks in general have been along the coast and on large rivers. Thirty-four per cent of outbreaks were attributed to drinking water.

*Read before the joint meeting of Water Works Officials and Connecticut Public Health Officials, Hartford, Conn., April 18, 1923.

Date	Location	Cases	Deaths	Medium by which infection was caused	Vehicle by which bacteria were conveyed	Determination of Source	Remarks
July-Dec. 1880	Manchester	63	15	Food	Fingers	Negative	Swath factory (laid on immigrant ship. All handled seasons in silk factory. Open sewer in rear of houses.
August 1882	Portland	60	11	Water	well 25 from Privy	Negative	Colony immigrants lately arrived. Open back privy.
1883	Guilford	6		Air	well from ceto pool 6 feet	"	Poor connection. Sink drain permitting food to be kitchen.
1883	Waterbury			Water	Cesspool	"	Attributed Soil Saturation.
Feb-Mar 1884	Middletown	7		Water	well 30 from source	"	washed. Permitted kitchen Slops used as Fertilizer to get into well.
August 1885	Middletown	16	1	Unknown	Unknown	"	No connection with water, milk or food detected.
Aug-Oct 1891	Stony Green	21	1	Water	Cashin from sand on rocks	Positive	Employee defecated on rocky ground. Was walking case. Infected cistern.
July Sept 1894	Stafford	21		Unknown	well 50 from Privy	Negative	Analyses and test did not show well as source.
October 1894	Middletown (Western College)	23	4	Food	Pratt's Beer 300 from Oyster Bea	Positive	House had 2 cases of Typhoid.
November 1894	New Haven	6		Food	Raw Oysters	Negative	Water, ice cream and celery eliminated.
April 1895	New Milford	20		Milk	Typhoid carrier on farm used privy or defecated in ground.	Positive	Typhoid carrier on farm used privy or defecated in ground.
Apr-May 1895	Stamford	386	26	Water	well 25 from Privy	Negative	Milk cans rinsed in well water. No conclusive evidence.

Date	Location	Cases	Deaths	Medium by which infection was caused	Vehicle by which bacteria were conveyed	Determination of Source	Remarks
July-Sept 1895	Danbury	41		Water	Disconnection	Negative	
1895	Easton	1		Unknown	Unknown	Negative	
Mar-May 1900	Forestville	48		Water	Faces from Milk water drinking	Positive	Submerged pipe line broken about Mar 31. By fresh Down outlet from factory about 300 above.
Sept 1894-July 1900	Do Norwalk	10		Water	Sewage	Negative	Discharge for sewer in Conn. Ave. formed fissures in pit through which sewage from sewer reached spring.
1901	Manchester	6		Unknown	Unknown	"	Attributed to garbage of privies in back yards. 60 cases last year before these were cleaned.
1901	Middletown	15		Food	Unknown	"	Hospital for insane. Probably brought in by visitors.
Apr-June 1901	New Haven	441	59	Water	Sewage	Positive	Privy open vault precipitous slope to brook, ground frozen, excreta thrown on surface. Heavy rain 18 days preceding outbreak, washed into reservoir.
Sept 1900-Nov 1901	Ridgefield	18		Water	Unknown	Negative	Attributed to wells, contaminated by cesspools.
Feb-Apr 1903	Bristol	84		Milk	Milk cans	"	Slops thrown on manure pile. Washed into spring used for rinsing cans.
February 1904	Waterbury	4		Water	Common drinking cups	"	Cups contaminated by men using toilets or shavings by leakage from houses on hillside above.
Oct-Nov 1904	New Haven	20		Food	Flies	Positive	Food exposed to flies. Open filth pits in dwellings adjoining. Typhoid at this place August & September.
Sept-Oct 1904	Canaan	15		Food	Flies	Negative	Cesspool and privy vaults in poor condition.
August 1905	New Haven	28	1	Milk	"	Unknown	"
1906	Canaan	3		Food	Flies	"	Probably ice from Blackberry River.

Date	Location	Cases	Deaths	Medium by which infection was caused	Vehicle by which bacteria were conveyed	Determination of Source	Remarks
August 1906	New Haven	37	4	Food	Fingers	Negative	Immature axes from almshouse on street contracted it and infected food.
July 1907	Danbury	12		Milk	Making case of Typhoid	Positive	9 cases took milk from same dealer who later came down with typhoid fever.
Aug-Sept 1907	Ansonia	33	4	Water	Unknown	Negative	Analyses of Spring in dry good, well poor.
August 1909	Woodmont	18	1	Milk	Bottles	"	One milk dealer sent ill with malaria. Bottles washed in kitchen. Privy in yard.
1909	New Britain	100		Water	Unknown	Positive	4 out of 81 wells analysed showed contamination when these were discontaminated. Case stopped in 1 month.
Apr-May 1911	Bridgeport	8	0	Food	Clams	"	All cases had eaten clams from same dealer.
Sept-Dec 1911	Torrington	329	35	Water	Unknown	Negative	While analyses of supply showed contamination, source of it was not determined.
Sept 1913-Nov 1914	Seymour	9		Food	Flies	"	Condition of kennels and stables very bad.
September 1914	Hartford	12		Milk	Carrier	Positive	Employee or dairy who helped with milking often found to be carrier.
November 1914	Hartford	34		Milk	Carrier	Positive	"
January 1918	Middletown	8		Food	Ice cream	"	Black tests and traces of colored chest pasteur.
July 1918	Litchfield	3		Water	Sewage	Negative	Drain pipe broken where it passed under corrugated lead pipe leading to septic tank.
August 1918	Andover	1				"	Wells of Summer boarding house had been discontaminated for 10 years. While tests were negative.
July-Sept 1918	Wallingford	18		Food	Ice Cream	"	Black tests and with of milk negative. After sale of ice cream was prohibited cases ceased.

be attached to this, due to the difference in method of reporting and investigating.

Seasonal variations are not distinctive enough to warrant drawing any conclusions. Apparently the major outbreaks occurred in the summer and fall months, August with 11, September with 14, and November with 10, having the larger number; though of the most intensive outbreaks, that at Stamford was in April and May, and the one at New Haven in April and June.

Thirty-four per cent of the outbreaks were attributed to drinking water, 16 per cent to milk, 36 per cent to infected food and 18 per cent to unknown causes.

The vehicle by which infection was conveyed was:

Drinking Water.....	8
Fingers	12
Flies	4
Milk Cans or Bottles.....	6
Common Drinking Cup.....	1
Contaminated Air.....	1
Unknown	14

Positive determination of the source of the infection was made in only 24 per cent of the outbreaks.

After considering this record, one cannot but be impressed with the large number of cases where the source of infection was not determined.

This cannot be attributed entirely to lack of personnel or thoroughness of investigation, for in New York City, where these should be ample if anywhere, in 1921, of 899 cases verified, the probable mode of infection was traced in only 40 per cent.

The question then naturally arises whether it were not better to acknowledge that positive determination is not possible with the present methods of investigation and either improve them, or abandon this line of investigation and devote our entire time and moneys to extending and improving methods of prevention which have proved successful.

Discussion: In discussing the above paper J. Doman, assistant sanitary engineer of the Connecticut State Department of Health, presented some interesting figures based on a comparison of the typhoid morbidity rates of various groups of towns in the state. The figures were for a four-year period and related to five regions chosen with reference to the amount of vacationing in the regions.

The first three regions, representing a combined population of about four hundred ninety-two thousand, had an annual morbidity rate per 100,000 of 19.35 or 61.2 per cent of the state average—(Continued on page 840)

How to Meet the Problem of the Delicate Child*

We Strike at the Roots of Physical Unfitness When We Begin the Teaching of Food to all Children, Whether They Are Undernourished or Not

By MARY SWARTZ ROSE, PROFESSOR OF NUTRITION, TEACHERS COLLEGE, COLUMBIA UNIVERSITY, NEW YORK CITY.

WE believe that there would be more happiness if there were more health. We also believe that there would be more wealth if there were more health, and with more wealth there should be still better health and consequently more happiness. It is a beneficent instead of a vicious cycle!

The author's experience with the delicate child as a public health problem practically dates from the organization of a little nutrition center in the vicinity of Columbia University, through which a group of us aimed to make available to the neighborhood the knowledge of better living and at the same time give Teachers College students an opportunity to learn how to serve a community most efficiently.

We organized some nutrition classes, of course, to study the problem of teaching nutrition to children. Circumstances soon so shaped themselves that we entered the big public school in the neighborhood (from which our children had been drawn); in cooperation with others and with the financial support of the New York County Chapter of the American Red Cross we organized nutrition classes in the various grades, between three and four hundred children being gathered into twelve or fifteen small classes. These children were selected with the assistance of the school physician, and were by him re-examined from time to time. We weighed the children weekly because we believe that systematic weight records help to an understanding of a child's health progress, because they interest the children in their own health, and, generally, interest also the parents. We made no special feature of single gains or losses in weight because we believe these are apt to be misleading and defeat the main object of our work. That such has been the case sometimes is indicated by this statement which I read the other day:

The health director feels that there has been altogether too much weighing and measuring in the schools and little has been accomplished as a result. The weighing and measuring has created a great deal of worry on the part of many parents [perhaps they should worry!] and the director would suggest that this practice be discontinued.

This is apparently a rebound from weighing unsupported by a proper educational program, which is always of doubtful value, useful as it is when properly incorporated in such a program.

Food Lessons Useful.

We gave the children weekly food lessons because we believe that this is one of the most practical attacks upon the general problem of nutrition. Malnutrition is a term generally used to describe the state of being below par when there is no specific disease. Weight is affected by numerous factors which may put a child physically below par, and because attention to diet does not immediately cause every child to gain, many are inclined to think that food has little to do with the undernutrition of children. This is because dietary factors operate slowly and their influence extends from one generation to the next in a very subtle way. According to several recent surveys, the major cause of absence from school is respiratory diseases. Nobody connects these with nutrition. But one does not have to work with experimental animals long to realize how greatly resistance to all sorts of infections is modified by a persistently poor diet. Our rats get into a state that makes me think over and over again of "snuffles" in children.

Some interesting new light is being thrown upon this increased susceptibility through the study of rickets. This is a disease which predisposes to respiratory affections. We know of two dietary measures which are preventive—cod liver oil and a suitable calcium-phosphorus ratio. The former

is easier to control than the latter. We produce rickets in animals at will on a diet low in phosphorus. But Dr. Hess discovered strains which did not respond with 100 per cent rickets like the others, and the explanation was found in the diet of the mother. It seems a long way from the diet of the mother to the colds of a child in school, but the matter will bear further investigation.

We know that the teeth of the child are practically determined before birth and shortly thereafter, and that a suitable diet is the most significant factor in good tooth production and maintenance. We know, too, the significance of the diet in regard to the control of goiter in school children, even though we find at the present time administration of medicinal iodine the best way to protect against this disturbance in goitrous regions.

For these and many other reasons, it seems that we strike at one of the roots of physical unfitness when we begin the teaching of food to all the children, regardless of whether they are undernourished or not. If we cannot at once take care of all the children, we are perhaps justified in beginning first with the less fit though I am not sure that the safeguarding of the fit for the future is not really more important. It is on this principle that we are giving food lessons now to an entire class instead of segregating the less fit for instruction. The less fit should have attention, but it needs to be more individualized. Some special classes for these children—a few of them—may always be needed.

No immediate striking gains in weight are to be expected from such teaching. Until we have carried some children through the whole elementary school it will be hard to evaluate this work. In the school of which I am speaking the teachers have come to believe in us, and want our lessons for their children. They say the children are better cared for by their mothers and the children certainly look better and behave differently. This year the

*Presented at the Massachusetts Public Health Conference, Springfield, Mass., April 28, 1923.

support for our special workers was unfortunately withdrawn and we have been able to have only the food lessons for the lower grades in the weekly hygiene period, supplemented by monthly weighing of the children. We are trying to make the little children understand that there are good reasons for a systematic and controlled diet, presenting in the lessons very small portions of the food which we talk about for each child to sample as well as discussing its relation to health and growth. The path in this sort of teaching is unblazed and we are giving it a great deal of time and thought and are going to visit the mothers and try to discover whether any of it is reaching the homes.

That something may be done for the actually unfit child through such methods is shown in reports that come in from home economics extension workers all over the country. These women are so far the best equipped as a class to deal with the educational side of the nutrition problem. One reports a county with 2,868 children 7 per cent or more underweight in which 620 were brought up to normal in nutrition classes.

Many attempts to eradicate undernutrition have been made through actual feeding of the children. This brings quick results in many cases. For two summers we cooperated with the summer play schools of the Federation for Child Study (until they got a nutrition supervisor of their own), conducting classes among the underweight children. These children were given a noon meal at the school daily, and the majority of the children, coming from very poor and generally ignorant homes, showed improvement chiefly to be attributed to the food served at the school. Our main function was to stimulate the children to eat the food, which they often did not like because they were untrained in eating habits and unaccustomed to the foods provided. One little girl said of a lettuce sandwich that she would eat the bread but not the flower. It took hard work to induce them to eat crusty rolls instead of soft bread, and to accept other innovations for their physical good, but as they did eat the food they made improvement.

Milk feeding in the schools is of the same nature as the school lunch. It ought to bring results where the children's diet has been inadequate in almost any way, and it brings results quickly in many cases. I think of the report, of one county, where the extension worker fed 551 children and 256 of them were brought up to nor-

mal weight by this simple procedure. We have no way of knowing yet how school feeding unsupported by education will eventuate as compared with an educational program unsupported by feeding, or how much more permanent the results from a combination may be. In rural schools the hot school lunch is an undoubted advantage to the children physically and it affords rich educational opportunities.

It seems to me that if money is going into any kind of a feeding plan, it would be much better spent if made a part of an educational program. I should be inclined to limit milk feeding as a general thing to the kindergarten and primary grades where one extra meal may be an advantage to every child and not to introduce it into those grades where the children can very well stand a three-meal-a-day program. Eventually they must learn to get their food at home and to select it more or less for themselves. In the early years there is a gain from having a staple like milk in school where the habit of liking it may be helped along by the group influence. In evaluating the milk feeding, we do well to remember that good diets for children under seven have about 40 per cent of their calories in the form of milk, and at no time during school life should the calories from milk drop much below 25 per cent. We must also remember that the underweight child often needs an extra meal which he can get only if furnished at school.

The majority of school children will grow if they have any sort of a chance. The underweights will fall into five classes:

- (1) Those who are naturally smaller than the average, but normal.
- (2) Those who are handicapped by some obvious remediable defect in their mode of life, such as lack of adequate rest or a persistently poor dietary program.
- (3) Those who are handicapped by some remediable physical defect, such as bad posture, bad tonsils and adenoids, defective eyes or feet, sequelae of disease.
- (4) Those who have some obscure physical handicap, as undetected chronic disease, such as tuberculosis or obscure physical defects.
- (5) Those who are congenitally weak.

The fourth group is the one the physician thinks most about in connection with malnutrition, and rightly. This class must have his help. It is not economical nor sensible to begin a health program without provision for a physical examination of the children, preferably all the children; where this is impossible the next best thing is to take the children who deviate

markedly from our best weight norms. We are quite likely to include in the net of 10 per cent underweight the ones in need of medical inspection. The physician must then sort out the ones who are not likely to respond successfully to any ordinary feeding or educational program, and to indicate what the line of attack on each individual child problem must be. For many it is the remedying of physical defects. These can generally be turned over to the nurse for follow up work. Often it is a combination of these things and bad health habits, so that if the child can at the same time have the benefit of an educational program so much the better.

The Congenitally Weak.

In the fifth and last class I put the child who is just "delicate," having a smaller vital spark than his companions, and needing scrupulous care for many years till he learns to take care of himself in such a way as to be well even though he may never be strong. To distinguish this child from the one who seems delicate but has some hidden remediable handicap is the severest demand we make upon the physician. Sometimes all the resources of a modern city hospital will be needed to detect the fundamental difficulty. But neither the naturally delicate child nor the one who has some obscure handicap will respond to simple feeding or education. These are the children who make some physicians say the delicate child is a sick child. By wise care there is always the hope that these children may in time outgrow their handicaps. Theodore Roosevelt is the shining example. But think of his driving ambition and of the wise father with every material resource who stood behind the puny child for years!

Far more hopeful is the educational work with the children who are not seriously handicapped. Health work for them is going to pay on a grand scale, if it can really establish habits. This is a hard thing for the school to do. One way to reinforce school instruction and school feeding is through cooperation of parents. But parents know even less than teachers about nutrition. We must so far as possible get hold of them and give them some "convictions" about their children's food. In one school lunchroom where they are trying to guide the children's choice, a child was refused more than one portion of Welsh rarebit unless she had permission from home to have more. The next day came the note from the mother:—(Continued on page 813)

The Camera and the Health Officer

A Screen Presentation of Insanitary Conditions Bears No Denial and Commands No Approval. The Photographic Witness is an Aid No Health Officer Can Well Ignore.

By C. V. CRASTER, M.D., D.P.H., HEALTH OFFICER, NEWARK, N. J.

IF we were asked to estimate in some way the value of the service rendered by the camera in the everyday life of the people there is no doubt that the part played by the "all seeing eye" in the administration of public health both by public and private agencies would be found to be of enormous influence. The old woodcuts so successfully employed in earlier days were, of course, crude affairs as compared with the artistic products of modern photography, but the lessons to be conveyed and the illustrations pressed upon the mind are inherently the same. The art of the old masters was far outdone by the improvements of photography, but the guiding principles by which direct and social benefits should arise

the truthful interpretation of the actual picture to be presented is a community asset whose value cannot be estimated.

Public health and the art of the camera have, so to speak, grown up together and if we further extend this dual growth to the development of the compound lens which was fostered by the demands of photography we can well see how closely it was related to the science of bacteriology upon which fundamentally our modern public health principles are built

the camera to the health officer there are certain kinds of inspection service in which very remarkable and striking results are possible. This does not, of course, include the almost limitless field of the motion picture. Particularly in field inspection service upon farms and dairies has the camera been of effective service. Photographs of this type have been surprisingly valuable. The pictures of unsanitary conditions around farm buildings seem to lend themselves to remarkable reproduction, seldom requiring an accompanying description.

The eye naturally looks for "spotless town" pictures of a dairy farm so that the shock is vivid and lasting when cow barns and yards are pictured as filled with mounds of

A slaughter house declared a nuisance because of undesirable noises and odors. Located in a populous section. Picture of antiquated buildings and insanitary surroundings led to its renovation.

and upon which they are maintained.

In no other municipal administrative function is there so much need of graphic representation of existing conditions necessary as in the case of public health. The oft-quoted question in inspection service of any kind is: "Were the conditions described really existing at the time of inspection, or is there not some material exaggeration in the report which does not faithfully represent the existing condition?" The reply is that the camera will show what the situation is and will actually convey a clearer picture than the eye remembers. The value of all photographs will depend upon how far the picture can reproduce existing conditions or whether it can delineate normal from abnormal states. The camera will sometimes, however, put an entirely different aspect upon an apparently clear cut picture of a violation of the law so that its public health value is negligible. In the many fields of usefulness of

manure, standing pools of sewage or rain water and the smeared and spotted walls and doors of dilapidated buildings. In this work nothing is so effective as the "before" and "after" pictures, in some instances the change is so startling as to test the credulity of the observer. Many of the dairy pictures show conditions upon farms nearly past belief. Here is a new barn unprovided with windows or any means of ventilation except by the doors which, of course, are closed in cold weather. It was naturally a simple matter to require large windows to be put in for light and a ventilating cowl on the roof. Almost an endless variety of insanitary conditions can be found upon the unsupervised dairy farm. The low type of house of the poor milk raiser is always a problem and at times the cows are better housed than the dairyman's family. In one of these places the whole dairyman's family was found infected with typhoid fever. In another

always will remain the same. It was found to be true of photography as of the work of the old craftsmen themselves that the simple and easily learned lessons could be demonstrated and illustrated by pictures which did not require to borrow from the grotesque or absurd to drive home a lesson. "Science," says Ruskin, "does its duty not in telling us the causes of spots in the sun, but in explaining to us the laws of our own life and the consequences of their violation. Art does its duty, not in filling monster galleries with frivolous or dreadful or indecent pictures, but in completing the comforts and refining the pleasures of daily occurrence and familiar service."

In this respect the camera may be said to "fill the bill" and to give that public service which no other art has so far approached in such full measure, in making life more cheerful, existence more endurable and health more permanent. This usefulness and

Litter in street and exposed meat on sidewalk in violation of sanitary code.

the house and dairy were in the same building with one member of the family suffering from the same ailment. The commonest form of insanitary condition found around barns was enormous accumulations of manure, undrained barnyards with pools of sewage or standing rain water. Photography brought out clearly the manure bespattered flanks of unclean cows used for milk production, the dirty hands and clothing of the hired help. The general results of good pictures of this type will create a more permanent effect than any plain statement of the undesirable conditions found.

"Even the dog looks unhappy," said one little boy in an audience viewing a series of farm slides, and he was right. Where farm pictures are used for lantern slides or publicity it is necessary to use some judgment in selection for an accumulation of horrors will tend to create indifference or even levity in the observer. "The worst of the dairy inspector," said one farmer, "is that he ain't got no sense of humor or he would have left us our old barns for us to laugh at."

In general sanitary administration the camera is an invaluable aid to the inspector in his work of marking down nuisances and violations of the sanitary code upon public and private property. Pictures illustrate this article in which a public abattoir became a community nuisance. The slaughterhouse had existed upon the location for a number of years in a crowded tenement and apartment neighborhood. It had been tolerated by its neighbors in spite of the bad condi-

and noises to be complained of continually. The photos very clearly show the ramshackle condition of the premises, and are sufficiently graphic as to conjure up all the other conditions complained of. The evidence of

A dairy barn showing conditions that were tolerated before the adoption in Newark, N. J., of the milk ordinance.

the pictures alone was sufficient to condemn this slaughterhouse so that the licensing body refused to renew the license, thus putting an end to an obvious plague spot. The city zoning law would, of course, have prevented the establishment of a new business in such a locality, but it is not retroactive and cannot automatically exclude existing business.

In clean-up campaigns the camera can convey very useful lessons of conditions found in back yards and lots. A good picture of such a place with the

caption: "Does your back yard look like this?" makes a most useful circular or poster for clean-up purposes.

Very effective indeed is the aid of the camera in depicting violations of the sanitary code in old buildings, defective and worn out storm leaders and gutters, sagging roofs and accumulations of waste water and mosquito breeding pools. All these seem to lend themselves to exact and clear portrayal. Many such photographs have been taken for production in court and have seldom failed to win drastic action to abate the condition shown. It is seldom, however, that an owner will refuse to clean up a yard or vacant lot when confronted with such evidence. In this regard one of our most constant offenders, the yard toilet or privy vault can be adequately handled by a good photo. Accumulations of rubbish and refuse in back yards are conditions easily remedied and although no direct health menace can be proved the unsightliness alone goes far as a powerful argument for removal.

Striking pictures have been obtained of unsightly conditions upon city sidewalks, especially where evidence has been desired of the exposure of foods in violation of the city ordinances. Some of the best examples of how the camera can demonstrate insanitary conditions are those in food stores and markets. The use of old buildings badly adapted for the clean handling of food is very frequently found in routine inspection. Such places spring up like mushroom growths over night with a coat of paint and an attractive menu upon the window but will seldom in-

Concrete evidence of reconstruction and general cleanup effected in same dairy shown in picture above.

dicade just what the kitchen is like. In one such instance illustrated the whole front of an old building had been ripped out to enable food to be sold on the sidewalk, which was itself a violation of the law. The kitchen of this restaurant was everything that such a place should not be. Old and scaling walls, rotten woodwork and floors loaded with roaches and other vermin made these premises impossible for use in the handling of foodstuffs.

It does not require any health training to see what is wrong with most pictures taken of the insanitary chicken markets, but one does find it difficult to convey to the observer the varied and intense odors present in such places; this unfortunately or fortunately, the camera cannot reproduce for us.

In one instance there was a vast accumulation of oyster shells upon a vacant lot in the vicinity of a lime burning furnace, the shells being used for the production of lime. The cause of complaint in this case was the stench arising from the decomposing animal matter upon the shells themselves. It required a photograph to convince the court that a nuisance existed. The camera does not always produce a picture of diseased meat sufficiently distinctive as to alarm the public from the cursory glance at the picture. Occasionally, however, a tuberculous carcass is seen so loaded with "perl such" or tuberculous nodules as to be clearly diseased to

Shows very clearly how tenement conditions can safely be condemned on the evidence of the camera.

the least informed of minds. In the carcass illustrated of a case of disseminated tuberculosis in a cow it is interesting to know that this reactor looked apparently healthy and had been giving raw milk for public consumption to within a few days of slaughter.

Among animal diseases cattle affected with foot and mouth disease afford very characteristic pictures. The foaming lips and the appearance of the animal standing on its tiptoes, due to ulceration around the hoof, are clearly seen in most pictures of this ailment. It is not always realized that good photographs can be taken of fumes and yet nitric oxide gas was very visible the day a picture was taken. These fumes were the result of certain war activities and caused a number of cases of unexplained poisoning. The company did not see the need for building adequate absorption chambers until court action was taken and forcible closing of the plant ensued until the necessary apparatus was installed.

The faithfulness with which the camera will decide where insanitary conditions exist is well shown in pictures. A particularly insanitary pool with the walls and steps in bad repair, with broken and chipped cement impossible to clean appeared in startling clearness in the photo taken which was directly responsible for the closing of this pool. A

good type of bath showing equally clearly illustrating the cleansable walls and floor of white tile, giving altogether a better appearance than the broken cement presented the other side of the picture and resulted in reform in this particular instance.

It is sometimes difficult to obtain a good picture of a small and ill lighted room, such pictures, of course, only being possible by flashlight. However, the brilliant light necessary will sometimes bring out into relief the main features of lack of space and overcrowding. Certainly the rooms represented in the accompanying picture are insanitary and unsuitable for living quarters and offer the best possible evidence of abuse of housing conditions. Pictures such as this have resulted with us in completely transformed living quarters.

It is hard to imagine what could take the place of the camera in depicting so clearly and accurately the actual conditions sought to be determined. The range of value of the camera is, of course, limited in certain ways but its usefulness as a graphic witness in nearly every branch of public health renders it well nigh indispensable to the Health Officer. It is probable that the moving picture will displace to some degree the present photograph especially in health publicity and school education for the public is becoming more and more dependent upon the "movie" for much of its everyday instruction and impression. For ordinary health administration, however, the photograph will remain a sure and certain aid to the inspector and the officer who requires evidence that no opposing testimony can refute.

Carcass of cow exhibiting advanced tuberculosis. The animal was a tuberculin reactor and had been milked up to a few days before slaughter.

Clothing and Health*

"Adequate Endowment for the Scientific Study of Human Raiment Is a Public Need—a Need Not As Yet Widely Realized"

BY LOUISE PHILLIPS GLANTON, DEPARTMENT OF CLOTHING AND TEXTILES, KANSAS STATE AGRICULTURE COLLEGE, MANHATTAN, KANSAS.

NOT many years ago, people, even doctors, and especially ministers, thought that the only function of food was to prevent starvation. Every one wanted to know "how low you could throttle down on high." The lower the grade of gas you could use, the better for you. True, some people flooded the carburetor and were accordingly out of order. Otherwise all maladjustments were the direct dispensations of Providence. In those days disease could not possibly be the result of faulty diet. Now everybody is expert at counting calories, and the various constituents of food stuffs have severally each its recognized influence on health.

For years a similar attitude was maintained with regard to clothing, which could harm only your morals, your pocketbook, or your husband's disposition. If you insisted on suitable clothes, you were doomed to bankruptcy in this world, and fire and brimstone in the next. No one thought for a moment that what you wore on the outside of your body affected in the least the inside workings of that body, except in the case of the temperature.

Now the light is coming! Dr. Woods Hutchinson says, "The chief quarrel which hygiene has with clothing is that there is too much of it—that garments come down too far, are too tight, too heavy, too hot. We do easily four times as much harm to our health by overloading ourselves with clothing and by overindulging

ourselves in the luxury of warmth, as we do by simply pressing the body at some single point like the waist line or the ball of the foot."

About fifty years ago, all the doctors and other learned folk began to suspect that constrictions of the body might have some hygienic significance. Corsets were therefore held responsible for all permanent displacements and maladjustments of the internal

The feet among civilized peoples are almost universally constricted in some way. Men have usually selected shoes wide enough but have neglected to insist on sufficient length. Colonel Munson of the United States Army says that when supporting the full weight of the body as in walking, the foot is at least an inch longer than when the body is seated. In

THE NATION'S HEALTH for June, 1923, Dr. Grossman shows x-ray pictures of a man's feet which are very badly misshapen by short shoes. Most cases of enlarged joints of the foot, bunions, corns, as well as ingrowing nails, and other malformations are directly the results of short shoes. This was not generally realized until the facts were brought out by shadow photography. Certainly Private Mulvaney was right when he said "a soldier on the march is no better than his feet."

It isn't so strange that men and women cramp their own feet and at the same time their style, but it does seem unforgivable that children's feet should be misshapen, maltreated. Shoes even comfortably long for growing children may in a few weeks become a menace to health and comfort, present and future. Pointed toes and narrow soles, while much to be deprecated, are not nearly so detrimental to health as restricted length and lack of ventilation. Patent leather is the most undesirable material for shoes. Dressed leather, suede, and fabrics of suitable kinds are named in the reverse order of their permeability of air.

Because the women of the past (and

Can one imagine a foot performing its full function encased in shoes like these? There is not a foot-shaped shoe in the entire lot.

organs in spite of the fact that such cases occur frequently among women who never saw a stay. "Society" women however went on compressing their waists until they found that the modern dances are quite impossible for a dancer tightly enclosed in stiff garments. Thus the corsetless vogue was inaugurated. Dressmakers now hang garments from the shoulders, or the hips where there are solid bones, not from the soft yielding waist.

*Read before the sixteenth annual conference of the American Home Economics Association, Chicago, July 30, 1925.

passing) generations, lacking economic independence, had to have a husband to produce the meal ticket, they followed the precedent set by the courtesans of France and wore high heeled shoes. It mattered not to the dear ladies that the demi-mondaine, if literature is to be believed, with one accord died young. Who shall say that the causes of many of the deaths were unconnected with the nervous strain due to maintaining an unnatural posture? Dr. Joel Goldthwait of the Harvard Medical College has cured a number of distressing disturbances of the alimentary tract by causing the patients to reassume natural postures through proper exercise and clothing. Zuntz and his associates in Berlin found that because of the increased muscular tension the maintenance of unnatural posture requires a measurable quantity of energy over that required to hold the body naturally. Various maladjustments of bones and muscles, especially at the ankle, are said to be due to the shifting of the weight caused by the change in the centre of gravity. Any garment which shifts the balance in any way is a disturber of nervous equilibrium.

Weight of clothing is another condition sedulously to be avoided, because of the added energy required to carry the burden and the consequent fatigue, physical and nervous. Beside the intrinsic weight of the fibre, of which linen is the heaviest in common use, texture is an important determining factor in weight. The more impervious to air, the greater the apparent weight of the fabric. Thus a well-napped blanket is less heavy than a closely woven unnapped fabric, when both occupy the same amount of space. Copeland says that one reason why silk is the most hygienic of fabrics is because it is the lightest in weight.

Lack of ventilation of the surface of the body has received some degree of attention from hygienists, among them Scherling, Aubert, Gerlach, and others. Kaposi quite definitely proves that a measurable amount of gaseous exchange takes place through the skin, which while only about one-half of one per cent of the total respiration,

Whatever the type of artificial support, the tendency is to weaken the musculature. While the lines of recent models approximate the natural contour of the body, it is far better to train the abdominal muscles to act as a corset than to encase the figure in constricting garments.

seems to be an exceedingly important function. Fourcalt varnished the surface of bodies of several animals. All of them sickened in a few hours, the results being cumulative. Several of them died with all the symptoms of suffocation. When the supply of

skin is comparatively small in amount but seems to be especially noxious if not evaporated. The most common way of preventing access of air to the surface of the body is by wearing many layers of fabrics more or less impervious to air, made into garments that fit closely and tend to restrict free movement of the air in contact with the body. Accordingly to Hutchinson, "The chest protector and the everlasting flannels are just as repugnant to an intelligent hygienic sense as they are to the 'sense in us for beauty,' and have done more harm to the species than any two beauty-born absurdities that can be mentioned."

In this connection the point may be made that low necked, short sleeved dresses are not the hazards that many would have us believe. The colds that are developed by the girls who wear evening dresses to dances are due either to the foul infected air of the ball room, to the fatigue from

the long hours habitually kept, or to a combination of the two. In their efforts to keep warm, men wrap themselves up like mummies in winter, because if they do not, they have been told they will take cold and die of pneumonia. Their sisters, their cousins, and their aunts fearlessly expose their wishbones to the wintry blasts, and wear silk stockings at Christmas

The human form divine lends very little grace to these monstrosities. Dress should at least be revealing enough to compel some attention to maintaining the integrity of the trunk muscles.

air is cut off from the surface of the human body, symptoms develop in every way similar to those manifested

time, and yet according to the United States Mortality Statistics for 1920, men died of pneumonia three times as often as women. In our college hospital last winter there were twelve patients with pneumonia and not a co-ed among them!

About twenty years ago Pflügge and his co-workers at the Institute of Hygiene in Breslau made a series of experiments which proved beyond the shadow of a doubt that nothing can make you dizzy, more nauseated, more exhausted than being too warm and damp from perspiration, with no movement of the air. This condition called "heat stagnation in the body" is responsible for many of the ills of life connected with the central nervous system, of which sunstroke is an extreme example.

The experiments of Pflügge are fully de-:—(Continued on Page 814)

by the varnished animals.

The amount of excreta from the

Ventilation of Department Stores

A System Which Provides Plenty of Fresh Air Without Drafts

BY A. M. FELDMAN, M.E., CONSULTING ENGINEER, NEW YORK CITY.

MANY department stores conduct frequent special sales on the first floor and in the basement. As a natural consequence these two floors are, as a rule, filled with crowds. Therefore it becomes an important problem to concentrate upon these in regard to a ventilating system.

The basements, as a rule, are windowless. Hence for their proper ventilation fresh air supply and exhaust systems should be provided in evenly balanced quantities. On the ground floors one has an additional vital fact to consider—the inrush of cold air through the entrance doors during the cold season which causes discomfort, especially to the sales force. On account of the drafts one observes in some instances, glass shields in front of the show cases which are situated near the entrances. An investigation would easily prove that this affords the clerks but an inadequate protection and that the sales people who work near the doors are all too often ill with colds, or other respiratory diseases.

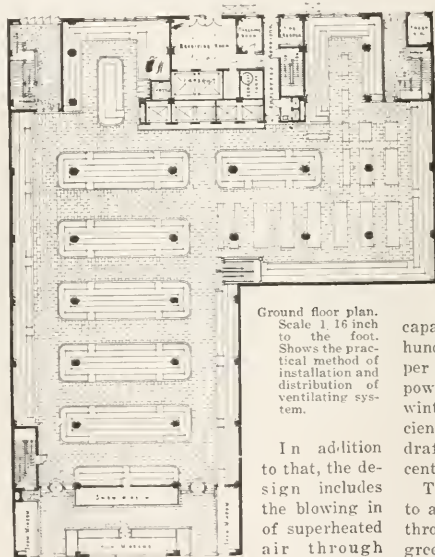

Entrances are, as a rule provided with vestibules. While these are heated there is always a rush of cold air into the stores resulting from the simultaneous opening of the outer and inner doors.

A practice has been developed by the writer, of designing the ventilating system for the ground floor of large department stores so as not only to provide an ample supply of fresh air, large enough for an unlimited number of customers and sales force, but also to eliminate all danger of such drafts as we have been discussing. Highly desirable results have been accomplished without the use of outer vestibule doors. The absence of these has added materially to the space surrounding the show windows, in consequence of which the prospective customers find added attraction in the window dresser's art.

The following is a technical description of the manner in which these results were obtained:

The ventilating system is so de-

signed that the fresh air supply is greater than the exhaust. More air is being delivered throughout the first floor than is taken out by the exhaust fan. The excess of air has to escape through the entrance doors, therefore when the latter are opened, the warm air from the store escapes, giving a warm greeting to the prospective customers. No drafts of cold air are rushing in on the sales force, who are thereby in a better physical condition to give full attention to the customers.

In addition to that, the design includes the blowing in of superheated air through registers in the ends of the counters, at the door, and also under the show windows just outside the entrance doors. Notwithstanding the absence of outside doors in the spaces between the show windows, the atmosphere around the entrance is kept comfortable warm and pleasant, thus inviting the street crowds to linger at the show windows, and adding to the probability of their entering the store to buy the things displayed.

This plan of ventilation has been successfully carried out in the Linder Department Store in Cleveland, and lately in the new Blumstein Department Store on 125th Street, between Seventh and Eighth Avenues, New

York City, both types of the highest development of such buildings.

The problem of the distribution of air in a store is a difficult one on account of the large open floor area. This was accomplished at the Blumstein Department Store in the following way:

Fresh air is taken from out-of-doors and warmed by passing over tempering and heating stacks and is discharged through a brick tunnel under the basement floor, then through two vertical galvanized iron risers, horizontal trunk lines and branches are distributed under the furred basement ceiling. Registers are evenly distributed over the entire ceiling and side walls for delivery of air to the basement, and branches are taken to first floor through vertical ducts around the walls behind the cases, discharging about 6 feet, 9 inches above the floor and through register panels in front of the show case bases.

The fresh air fan is of a capacity to deliver a maximum of one hundred thousand cubic feet of air per minute, requiring a fifty horse power motor to drive it. During the winter months it was found that sufficient air is delivered without causing drafts by running the fan at 70 per cent of its maximum speed.

The outdoor air is heated in winter to about 74 degrees F., and delivered through the registers at about 68 degrees F., which was found satisfactory for maintaining the temperature in the store at a uniform temperature around 70 degrees F. The temperature is maintained automatically by means of a thermostatic control system. Space has been provided between the tempering and heating stacks for the future installation of an air washer, which has been temporarily eliminated from the original plan.

In summer the fan is kept running at full speed, thus causing a pleasant current of air. The exhaust air duct work is distributed entirely through underground tunnel and branches under the basement floor and brought up through the floor in galvanized duct casings that are incorporated in the

counters, the tops of which are utilized for the display of goods.

The exhaust ducts for the first floor are carried up along the building columns and are incorporated in the fire-proof protection of the columns.

A brick shaft was built around the steel boiler stack, and as there was enough free area, the space was utilized for the exhaust air by connecting it to the tunnel. The exhaust fan was placed in the roof penthouse.

Thus the foul air is discharged above the roof of the building. The heat of the stack adds a great deal to the motive power of the exhausting effect over and above what the exhaust fan was designed to do.

Messrs. Robert D. Kohn and Charles Butler, New York, were the architects of the building and A. M. Feldman, consulting engineer for the mechanical and electrical equipment.

The Stork Adopts Installment Plan

IN order to enable prospective mothers in moderate circumstances to afford hospital care, the New York Nursery and Child's Hospital adopted a plan some two years ago, to lighten the financial burden of hospital confinement. Patients, already required to register several months before their babies are born, are by this plan, encouraged to pay for their hospital care on the installment plan. Prospective patients are thus enabled to pay for their care in advance of their confinement, and so be relieved of the massed expenses usually attended a visit of the stork.

The trouble with the usual installment plan is that payments are made after the service is rendered or the article in use, thus removing the chief incentive to thrift. The financial burden of childbirth was bad enough at pre-war prices. Today it is often catastrophic. The expense of caring for a baby after it is safely delivered is all that most families of moderate means can stand, without starting off with a lump charge of from one to several hundred dollars. And the birth of a child is something that most families want attended with dignity and independence. It is something for which they do not want charity or reduced rates. They want the best of skill and the most comfort their means will afford, and this Hospital has accommodations for all incomes, from surtaxable to invisible.

This provision is intended to spread the cost over several months and have it out of the way when the new baby's demands on the family exchequer begin. Experience with it has already shown that ward patients welcome it

as a means to paying their full way without breaking them, and private patients as a means of availing themselves of the security of hospital care at a pre-determined and prepaid expense. Seven dollars a month for seven months is not much of a burden for the ward patient, nor sixteen dollars a month for the private patient;

*Nursery and Child's Hospital, New York City, devises a partial payment scheme to enable mothers to pay for hospital care. It is so arranged that the hospital account is out of the way by the time the new baby's demands on the family exchequer begin.

and many use the plan to provide better accommodations than they could otherwise afford. The general plan is to divide the entire two weeks' charges into as many equal monthly installments as the date of registration permits.

If patients knew the added feeling of security that the doctor has when his patient is in the hands of a hospital and nursing staff ready at every moment of the day and night for all comers and every emergency, few would elect to try to turn a household bedroom into an operating room. If it were an appendix, now, they would not hesitate; but the trouble with an appendix is that you can not tell seven months ahead that it is going to require attention. That is why the advanced installment plan is adaptable only for a maternity hospital, and why the New York Nursery and Child's Hospital can make it possible for any mother to have the comfort and security of hospital

care at a smaller burden for her husband than if she remains at home, where domestic burdens are added to financial.

Hygiene of the Workshop

A recent radio broadcast under the auspices of the New York State Department dealt with the effect of proper sanitary conditions of the workshop in promoting the health of the worker and the consequent influence upon industrial production. The author, Dr. Leland E. Cofer, formerly health officer of the port of New York and now director of the division of industrial hygiene of the New York Department of Labor, defined the sanitary and insanitary workshop, as applied to nonhazardous trades and gave a popular discussion of the dangerous trades.

Dr. Cofer continued:

A satisfied man is less likely to leave his job than a dissatisfied man. The worker will be satisfied just in proportion to the effort made by his employer to make his surroundings favorable. The sick or tired worker reduces output and increases labor turnover while the healthy, satisfied worker increase production, advertises his employer and lowers the cost of turnover. Employer, Listen! Eliminate the unhygienic conditions in your plant! Furnish good ventilation, proper lighting, cleanliness and accident prevention devices! Refer your employees to a physician! Maintain an educational department, however small! Teach your people how to work! Teach them how to take care of their health! Teach them how to avoid accidents! Teach them by posters, by lectures and by personal talks! It will pay all around.

Now finally a word as to the responsibility of the worker. Remember, Mr. Employee, that all industry is becoming more and more specialized, and it is becoming more and more necessary that the individual worker be closely fitted into his part. It is frequently found that factors such as wages, social position or relatives at the same work influence a person more than anything else in choosing an occupation. The question of the suitability of the employment to the person's physique or temperament is too seldom considered. The employer is therefore applied to by persons who are ignorant of the requirements of the work and who are accepted simply on account of the necessity of the moment.

The workers, especially in dangerous trades owe it to themselves to get all the sleep and rest they can and to endeavor to keep themselves in the best possible physical condition.

About sixteen per cent of idiots are ambidextrous—a proportion far higher than found among normal people.—Church.

Rural Health Problems From the Massachusetts Viewpoint*

Health Problems, Rural or Urban, are Primarily Economic, Given a Satisfactory Basic Income, Standards of Living Improve

MASSACHUSETTS COLLEGE OF AGRICULTURE, AMHERST, MASS. BY JOHN D. WILLARD, DIRECTOR OF EXTENSION SERVICE,

IT may have occurred to you to wonder why this subject, "Leading Problems of Health Work From the Massachusetts Viewpoint," should be assigned to the director of extension service at an agricultural college, rather than to a medically trained specialist. It has occurred to me to wonder why; whether in my own person I am supposed to embody unusual experience of ill health, or good health, or both; whether it was because I have lived under as rural conditions as will be found in Massachusetts, and have seen them at their best and worst; or whether it is because my official relationship has afforded the opportunity for studying these conditions and coming to a layman's conclusions, with the usual degree of inaccuracy which laymen reach in passing on technical matters. Certain it is that anything which I may say is not to be construed as the technical opinion of one medically trained, but rather the impression of a lay student of rural affairs.

The nature of my work as Director of Extension obliges me to take different viewpoints on different occasions. In order to inform people concerning our rural opportunities and problems, it is sometimes wise to point out the differences between city and country; at other times it is necessary to emphasize similarities. Something of each process is necessary and desirable in this case. The people who dwell in cities, whether born there or elsewhere, are not vastly different from the people who dwell in the rural sections. This is true today, as never before, because of the free flow of population. I realize that

some anthropologist may challenge this by telling me that intensive inbreeding or, at least, line-breeding of rural sections has evolved physical types and mental types quite different from the composite type of the city. To him I would reply that while this was true twenty-five, fifty and one hundred years ago, it is much less true today because a considerable portion of city people were born in country

the human beings in the city?

It is in the artificial things that we note differences. Because of the intensity of problems in cities, much more has been done toward meeting them. The water supply, the milk supply, the sewage disposal, and even the conditions of housing are more or less rigidly supervised. Cities have been obliged to create facilities for meeting emergencies of individuals and families; as in the maintenance of both public and private hospitals, dispensaries and clinics. The number of organizations engaged in social service is legion. Witness the thickness of the volume which lists the charities of the city of Boston. Furthermore, the number of doctors within reach is adequate to meet the ordinary emergencies. But those of us who have lived in the country know what it means to be six to eight miles from a doctor and twenty miles from a hospital or a nurse.

Furthermore, the facilities for education and spread of information are vastly better in the city than in the country. The

Cannot Superimpose Health Conditions

TO INCULCATE a general and compelling desire for improvement of health conditions is the crux of health work. It is the people themselves who solve their health problems, under the guidance of experts.

Communal matters receive community action because the community feels the need. Other matters of home construction and personal habit and hygiene can never be successfully legislated or policed into existence; they will come only when the rank and file want them.

Districts and many of our present country families originated in the city. It is a commonplace to find that the majority of old families in a country town are no older than two generations in that particular town. It would be correct to draw a distinction between Massachusetts and central Vermont in this respect, for in central Vermont it is true that the Anglo-Saxon stock has persisted with much greater vigor and much less change than in Massachusetts. May we assume, therefore, that the human beings in the country, whose health we are considering, cannot be held to differ in any material respect from

daily press, the movie screen, the organized course in public schools, the billboard, the sermon, all reach numbers of people quickly and effectively. Furthermore, the people of cities are in constant unavoidable contact with their fellowmen and must as a matter of course, exchange a great deal of information (unfortunately, misinformation as well) concerning all matters, including health.

Another factor of quite considerable importance in cities is the opportunity for a balanced diet. Those of us who have lived thirteen miles from a railroad, as I have, will need no argument to convince us of the advantages of

*Read at the Massachusetts Public Health Conference, Springfield, Mass., April 27, 1923.

good vegetable markets and good fish markets. It is not merely a question of ability to provide variety in the diet, but of ease, convenience, and economy of so doing. Where supplies are available in profusion and at reasonable prices; where they are thrust upon us by the push cart vender, it is much easier to include variety in the diet than under conditions of the average isolated farm.

A definition of what we mean by "Rural" may well be called for. We cannot use the Federal definition which classes as rural all inhabitants of incorporated places with less than twenty-five hundred population; for in this Commonwealth it is the township that is incorporated, and there is very little separate incorporation of villages except as fire and water districts. No distinction is made by the census on the basis of occupation or mode of life. Mill villages like Erving and Hinsdale are counted as rural, while no rural population is recognized in Hadley, or Deerfield, or Ludlow, or Agawam. For this discussion let us include those people living so far removed from sizeable villages that they get neither the public utilities such as town water, sewer and lights, nor the stimulus that comes from human relationships in centers of population.

What Are Health Deficits?

What, then, are the health deficits of the rural regions? These deficits are the problems?

We note a lack of understanding that things are wrong and at the same time improvable. Lack of doctors and nurses and dentists and oculists is more or less keenly felt, but the lack of ventilation, of sanitary conveniences, of succulents in the winter diet, have been so traditional and so unavoidable in many cases that they have come to be accepted as the normal and proper condition. Some of these items just listed must be given a little more direct consideration.

Lack of doctors in the country is a real fact and a real problem. Having driven and tramped through the winter snows and spring muds of Western Hampshire County with my doctor neighbor, and knowing rather intimately the fiscal rewards of his hard labor, I can easily understand why doctors do not stay in the country. The same reasons also cause the shortage of nurses in the country.

Lack of conveniences in houses is all too obvious. The old New England farmhouse is too sturdily built to be abandoned and was built without thought of central heating plant,

plumbing, or ventilation. Lack of adequate running water supply is probably the most serious deficit in our country houses; for the water supply determines the possibility of toilet, bathtub, washtub convenience, and hot water at the sink. Most farmhouses can be made comfortable and sanitary. Many already have been so improved.

The opportunities are at hand for abundance of variety in the diet; yet too many rural families live in winter too much on the fat of the land, namely, home-cured pork; with too little of bulky vegetables or fruits.

But underlying all this is the real problem: the *farm income*. We may even wonder whether those who cannot buy toilets and bath-tubs are better off for being conscious of their privations. The real fact is that the cash return for working in the country is in many cases so small that it has compelled rigid economy in many families, and the foregoing of many things which to us would be commonplace necessities. In the early days of our colonial history the life of all was primitive. The wash tub in which the poorer farmer took his bath in the kitchen after the family went to bed was but little poorer than the wash tub in which the squire took his bath. The pump in the back yard of the poorer farmer, if he had a pump, was probably just as good as the pump in the back yard of the squire. If he had an old-fashioned well-sweep it was almost as good as a pump. The distinction in convenience of housing was slight. But from that time to this, advances have been very great in the field of mechanical aids to the comfort of life. Our eating, sleeping, working and playing are, as at present conducted, all dependent on mechanical devices which we are pleased to call civilized. It is in this matter of mechanical equipment that we note differences between city and country. The amount of money handled in the country is slight as compared with the amount of money handled in the cities. The result must necessarily be that the amount of mechanical equipment purchasable in the country is less than in the city. It is further evident that where homes are isolated such services as water supply and sewage disposal cannot be undertaken on the community basis. These provisions must be for individual farms at individual expense.

It is also important to remember that much of the country in New England that was first settled should never have been developed as farm

land. It never was created for farm land and never can be made into prosperous farm land. A great many of the so-called farm homes are in fact the homes of laborers, skilled or unskilled, who get a part of their living from the soil, but the major part of it from work in the woods or on the highways or elsewhere. It is a mistake to consider these homes as farm homes. They are, however, an essential part of the health problem because people live in them and the people who live in them are entitled to good health. Many of our western Massachusetts towns have large areas which are good woodland and nothing else. Some whole towns are nothing but potential forest land. If this forest land is to be properly utilized people must live in these towns. There must be man-power to harvest the forest products and to keep the roads in repair. Where we men, women and children, and where families exist must be provided the elements of civilization: to-wit, sufficient income to get the necessities of life, adequate channels of transportation, adequate schools, adequate religious opportunities, adequate recreational opportunities, and adequate opportunities for the maintenance of health. But the income is the basic problem.

Income Is Basic Problem.

The same lack of total resources which has retarded the development of the housing and which has held back people from the knowledge of many things urban, has also held back the development of school and church and recreational opportunities. All the elements of the well rounded country life are closely linked together in this problem. The common foundation on which it must be built is the income of the average family. It is useless to suggest bath tubs and toilets and running water and revised systems of heating and ventilation if there is no money with which to install them. A study of those regions which are agriculturally prosperous shows quite conclusively that as the fiscal basis of life becomes adequate, these comforts of life are appreciated and provided. Homes in our prosperous country sections are just as well equipped as homes in town; teeth are cared for; glasses are secured when necessary, and the routine of life is put on a more rational basis.

Our extension work is not essentially health work. It is the effort to carry out the provisions of the Federal appropriations by which it is in part supported; namely, "to impart useful and—(Continued on page 831)

Child Health Work in Belgium

The Commission for Relief in Belgium Educational Foundation Does Extension Work in Health Education and Provides Exchange Scholarships and New Opportunities for Study

By JULIA B. TAPPAN SPECIAL ADVISER, CHILD HEALTH SECTION, C. R. B. EDUCATIONAL FOUNDATION, BRUSSELS, BELG. UM.

THE Commission for Relief in Belgium, of which Mr. Hoover was chairman, was founded during the war to administer relief to the people, especially to the children, of Belgium. The Commission for Relief in Belgium Educational Foundation was organized as an outgrowth of this relief work.

The plan of the C. R. B. Educational Foundation provides for direct aid to the universities and technical schools of Belgium, financial assistance to students of limited means, support of institutions devoted to child welfare, and the promotion of good will between Belgium and the United States.

The exchange of professors and students, as one of the developments of this plan, has not only linked the universities of Belgium and the United States more closely together through the interchange of educational ideas, but has also helped in promoting a spirit of good will between the two nations.

In 1922 the Foundation entered into the making of plans for a Child Welfare program in Belgium as provided for in Mr. Hoover's outline of activities. Following the basic idea that extension of education in Belgium is the best use to which the funds can be applied, the corner stone of the program is the health education of all Belgian school children.

In the summer of 1922, Miss Sally Lucas Jean, director of the former Child Health Organization since January, 1923, the Health Education Division of the American Child Health Association was asked by Mr. Hoover, president of the C. R. B. Educational Foundation, to visit Belgium and investigate what was being done for

the health of children of school age. Miss Fanneal Harrison, who had carried on Child Health Work in Europe for the Red Cross during the past four years, accompanied Miss Jean. As a result of this visit fifteen Belgian child health workers, teachers for the most part, were selected for a year's study of health education in the United States as holders of C. R. B. Educational Foundation fellowships. This study was to include not only university work, but actual field work and observation. These young women arrived in the fall of 1922. Their names

work in the country. They also had an opportunity to visit schools, social agencies and child welfare organizations in Boston.

In June some of the students were given a taste of American Camp life at Camp Andree Clark, the Girl Scouts' National Camp.

Miss Fanneal Harrison, who accompanied Miss Jean to Belgium in the summer of 1922, supervised the work of the Belgian Fellows until her return to Brussels early in February, 1923, as director of the child health section of the C. R. B. Educational

Foundation. She is making a thorough investigation of the field of child health in order to make recommendations for a definite program for the Foundation. Miss Harrison was accompanied by Miss Catherine W.

Gavin as associate director. Since her departure the work of the Belgian students has been supervised by Miss Julia B. Tappan, who was recently in charge of Health Education Work in the United States Bureau of Education.

Belgian Nutrition Survey

As one of the first steps in planning a Child Health Program in Belgium, Miss Harrison recommended that a nutrition survey be made to include both the food habits of the Belgian children and the food resources of the country, especially the milk supply.

Miss Flora Rose, professor in the home economics department of Cornell University left for Belgium early in April to make this survey. In one of her unofficial letters she mentions the amazing custom of some Belgian farmers who buy fresh cows from Holland, milk them dry, and then kill them for food. This may partially

and the universities to which they were assigned are shown above.

Their academic work has included courses in personal hygiene, nutrition, community hygiene, health of childhood and adolescence, mental health, school hygiene and physical and practice teaching. They have had numerous opportunities to observe and practice health teaching in the classrooms. Authorities on various phases of education and social work have conferred with them and have given them an opportunity to visit and become familiar with special fields of activity.

During May all the students were located in Boston in order to put in a month's intensive observation and practice teaching in the schools of Newton, Mass. There they were under the direct supervision of Miss Mabel Bragg, assistant superintendent of the Newton, Mass., schools, whose program of health education is one of the foremost examples of this type of

*Resigned December 31, 1922.

†Transferred to Columbia University, January 1, 1923.

account for the poor milk supply in Belgium.

As another step in making possible a country-wide program of health education in the schools, Miss Mabel Bragg went to Belgium in August to give an intensive course in methods of health teaching for normal school teachers. The normal schools will thus be prepared to disseminate this knowledge and the classrooms of the returning Fellows will serve as demonstration centers of Health Education in action.

The Foundation is naturally working closely with the existing child welfare organizations and educational institutions in Belgium. Three delegates were sent to the International Health Education Conference in Oakland, Cal., June 28 to July 6. These delegates were Mlle. Kaiser of *L'Oeuvre Nationale de L'France*, who is a director of a colony for debilitated children; Monsieur Dronsart, director-general of the Red Cross in Belgium, and Monsieur De Pauw, a member of the Ministry as director-general of normal teaching in Belgium. These delegates were afforded an opportunity

to visit important centers of health education activities in the United States such as Trenton, New Jersey, Newton, Massachusetts, and Iowa City, Iowa, before attending the conference.

Finally, as a result of this program of preparation there were placed in Belgium at the beginning of the school year, fourteen young women trained in health education theory and practice through a year's study; a number of normal school teachers familiarized with health teaching methods through Miss Bragg's short intensive course; and a group of important institutions acquainted through their delegates, with health education programs developed in the United States and in other parts of the world. In addition to this there will be available an intimate knowledge of health education possibilities in Belgium and an authoritative survey of food resources and food habits, through the studies of Miss Rose and Miss Harrison.

All this is the seed. The soil lies in every classroom in Belgium. The flower? Ah, we must look for that in each succeeding generation of Belgian men and women.

50 per cent of the private physicians reported and it is estimated that the total returns (from 21,000 cases) represent approximately 75 per cent of all the cases actually treated by medical men during the period in question. The number of new cases treated during this month would correspond on the same assumption (that they represented 75 per cent of the total) to about 80,000 new cases of venereal disease per annum coming to physicians for treatment, giving the rate of about 6,000 such cases per 100,000 population of which less than one-third are syphilis, somewhat less than two-thirds gonorrhea, and about one-eighth chancroid. It is rather interesting that in some districts, as that of Carpathian Russia, the proportion of syphilis is materially higher, probably as a result of extra-genital transmission. The actual returns (without allowance for non-reporting physicians) averaged 169 per 100,000 for women, 716 for men and 437 for both sexes. By marital condition the rates for both sexes are: unmarried, 704; married, 431; widowed, 115; divorced, 977. Maximum age incidence occurs between the ages twenty and twenty-four, the rate for this age period being 990 for women and 3,300 for men. Particularly interesting figures are given for incidence by occupation, the lowest rates occurring in agriculture, forestry and the textile industry (in the neighborhood of 100 cases per 100,000) the highest rates among those working "for hire," 16,300 cases per 100,000; the banking trade, 8,740, and in the army, 8,070 per 100,000. It is of some interest to note that an analysis by Dr. Pelc in another chapter shows that the official venereal disease statistics for the Czechoslovakian army are very much lower, amounting only to 2,640 per 100,000 and on this latter basis the Czechoslovakian army shows up exceedingly well, with less than one-third as much venereal infection as the American army and only half as much as that of Great Britain. It seems probable that the questionnaire results are nearer the truth in this case. In any case they constitute one of the most interesting and suggestive studies of venereal disease incidence which has been made anywhere throughout the world, and Dr. Pelc and the Ministry deserve the thanks of all workers in the social hygiene field for the substantial contribution they have made.

Rutherford County, Tennessee, has been chosen by the National Child Health Association for a five-year health clinic.

Venereal Disease in Czechoslovakia

THE Division for Study and Reform of Health Activities of the Ministry of Public Health and Physical Education of Czechoslovakia has just published a monograph by H. J. Pelc on the venereal diseases in the Czechoslovakian republic which is one of the most important contributions yet made to the study of the venereal diseases as a public health problem. The parliament of the new republic as early as November, 1918, passed a resolution calling for a revision of the laws dealing with social hygiene and on July 11, 1922, an ambitious and far-reaching law was enacted which abolished the previous system of regulation of prostitutes which had existed under Austrian regime, forbade the establishment and maintenance of houses of prostitution and provided so far as venereal diseases are concerned for anonymous notification, compulsory examination of suspected persons, compulsory treatment of those infected and free treatment for the indigent with instruction of young people at school and after leaving school in regard to the important problems of social hygiene. It would seem from Dr. Pelc's review of existing machinery for combatting venereal diseases

that this law is still largely a dead letter a year after its passage. It is probable that Mark Twain's remark, "There is no end to the passage of laws and no beginning to their enforcement" applies to human nature the world over. It is encouraging to note, however, that thirty-eight Wasserman laboratories are in existence in the republic with twenty-one dispensaries treating some 10,000 cases a year, and a great many other cases are treated under the sickness insurance funds which include in the scope of their operation something like 53 per cent of the population of the republic.

Dr. Pelc's review of the work of public and private agencies in combating venereal disease in Czechoslovakia is chiefly of local interest. The second part of his report dealing with the statistics of venereal disease is of far more general interest. The ministry of health early in 1921 very wisely undertook to obtain some information in regard to the extent of the problem that confronted them and through a questionnaire canvass attempted to obtain full reports from clinics and physicians in regard to all the cases of venereal disease treated in the month of February, 1921. Over

The Health Administrator's Dilemma

The Chief Problem of the Health Administrator is How to Stem the Rising Tide of Public Demand for Preventive Therapeutics

BY EUGENE R. KELLEY, M.D., MASSACHUSETTS STATE COMMISSIONER OF HEALTH, BOSTON, MASS.

IN NEARLY all of the states of this country a superficial historical inquiry will demonstrate that the impetus which resulted in the establishment of a state board of health came from members of the medical profession, usually from the state medical society as an organization. In the establishment of city or town boards of health the same influence can be traced. Moreover, in many, probably most states, it will be found that prior to the statutory establishment of "boards of health" the state medical society through standing committees had made itself responsible for some of the most fundamental functions of health departments. These committees reported regularly upon epidemics, incidence of disease, sanitation of public buildings, sanitary conditions of "vaccine farms" and other matters of sanitary character and interest.

As the legally created "boards of health" came into existence and their powers and duties gradually took form under successively enacted statutes, it is easy to trace for many years a line of demarcation between the field of the private or individual practice of medicine and of these newer public bodies originated for the purpose of carrying out certain obviously needed medical and sanitary services which the doctor either as an individual or through his professional organizations was not in a position to handle. Roughly speaking, on the one hand it became the duty of the "boards of health" to collect, compile, and publish the vital statistics, abate nuisances, consider water supply problems, and be responsible for the "con-

tagious" aspects of disease from the community or "mass" point of view. On the other hand, it was the duty and privilege of the practising physician to handle all "individual" or "personal" problems of disease or health.

As time has gone on there has been a gradual blurring of these lines of distinction. Coincidentally there has

ance practice," "industrial medicine," etc., as well as a very new interpretation of a very old term, "state medicine." All these things are at once a cause and result of a new alignment of ideas relative to all phases of the subject of health and disease.

In this new alignment of ideas relative to health, health departments, disease prevention, and the place of the medical profession therein, one of the most striking and significant developments of late has been the extraordinary growth of interest in health questions by the general public. Health has all of a sudden become really popular and the true explanation of many of these developments which send some of our clinical brethren into a frenzy has been the pressure of popular interest bringing these measures into at least experimental existence, and not because health administrators have cunningly conceived them and foisted them upon an unsuspecting world. In fact, all over the country the health administrator, trained in medicine himself, usually with a background of actual experience in medical practice, and sympathizing in many ways with the instinctive re-

A Pressing Problem In Relationships

THE problem of what the health department and the physicians are going to do to each other and for each other during the months and years to come is even more pressing than the "system," whether state, community or industrial, under which health service is to be administered.

But whatever the machinery of health departments, the aim of medicine no less than health administration must be increasingly the recognition of disease at its inception—that is, prevention and cure at the curable stage.

It is far less to the point for the persons concerned to impugn one-another's motives than it is to face the situation frankly and make an effort to find a real solution.

arisen a great mass of "hygiene" specialties, all receiving recognition as part of the integral programs of health departments. There has also come into existence a now very considerable number of so-called "voluntary" health organizations, good examples of which are such organizations as the National Tuberculosis Association or the American Child Health Association.

Along with these developments have come a certain almost inevitable amount of clashing of viewpoints and general friction and the coming into common medical parlance of such terms as "health insurance," "insur-

action of the medical profession toward conservatism in these fields of public health adventure, is usually exercising a retarding or cautioning influence upon many of these projects. This he does, not because of lack of sympathy with the objectives sought in these newer proposals in health conservation, but because his training and experience alike cause him to be very skeptical whether the methods proposed by many enthusiasts in the health field are sound, trustworthy, and in harmony with the best spirit of our institutions and social traditions.

This development was recently epit-

*Read at the second annual Conference of Health Officers and Public Health Nurses, Lansing, Mich., December 4-8, 1922. Reprinted from *Public Health*, the Bulletin of the Michigan Department of Public Health.

omized and the possibilities involved in the extreme application of some of our most popular brands of health endeavor cleverly satirized in an address by Dr. B. L. Bryant, secretary of the State Medical Association of Maine. Speaking more particularly of the developments of state boards of health, but by inference and context including all the activities of local Boards of Health as well, he said:

At first the duties of these boards were very few. They looked after the water supplies and the sanitation of public buildings and institutions. They helped in the control of epidemics of contagious diseases and later started departments of vital statistics. The necessary laws governing this work were written and placed on the statute books through the efforts of the physicians.

From this small beginning the work of the state boards of health has increased and their functions multiplied, until now their departments are many and their local workers, physicians, nurses and engineers are found in every community of a state. A new field has been opened to physicians in this work of public health. They are employed and their salaries are paid by the state. They are supposed to look after the welfare of the citizens in the field of preventive medicine and sanitation.

Some friction has arisen between these state boards and practising physicians from attempts of the former to limit the activities of the physicians by statutes of regulation, which in their endeavors to enforce has aroused in some instances a feeling of resentment. There has also been a tendency in some states to depart from the legitimate field of preventive medicine and sanitation into the province of therapeutics or treatment of disease. While willing for the most part to yield to the state the authority which seems best for the good of its citizens in preventive measures and the care of the indigent and the insane, the physicians are jealously guarding their independence in what they consider their own individual field of contact between doctor and patient, that of diagnosis and treatment of the general ailments and afflictions of mankind.

In other words, while willing to cooperate as much as possible in a movement which they themselves originated, the physicians in general are making every endeavor to steer clear of state controlled or state medicine which has been so destructive to the medical profession and to the general public in so many European countries.

In more recent years the people as a whole have come to take a decided interest in matters pertaining to health. This interest has continued to increase until innumerable so-called voluntary health organizations have sprung up and continue to multiply all over the country. Anti-tuberculous, anti-venereal, child welfare, maternal welfare, family welfare, baby welfare, in fact a more or less free fare and invitation is sooner or later offered to every one to join one of these

groups on the free road to health.

The Free Road to Health

The prenatal clinic cares for the child in its mother's womb and guides it into a hostile world. It is received in the motherly lap of the baby welfare clinic and tenderly cared for. It receives its nourishment from the warm and hygienic bottle, prepared in the baby milk laboratory. Its tottering steps are guided by the helping hand of the child welfare society. In due time the child enters school where he is welcomed on the threshold by the school nurse and introduced to the school physician. He is vaccinated against smallpox, inoculated against typhoid, is given the Schick test and made immune to diphtheria. His teeth are looked after at the dental clinic, and his tonsils and adenoids are removed at some hospital outpatient department. His eyes are examined and possibly fitted to glasses. Thus equipped and prepared he at once starts to do his health chores. Found underweight he enjoys for a time the luxury of an open air school under the supervision of the nurse and physician of the Anti-Tuberculosis Association. Thus is he guided through school and may take a chance at college. If he escapes here for a moment from his guardians and falls into evil ways there are free clinics provided for even these emergencies.

Safely passing his health inspection and eugenic society examination, wedlock is entered. In due time his wife becomes an attendant of the maternal welfare clinic. His health is guarded by his periodic health examinations. He is looked after at his work by the industrial nurse and then is prescribed for by the industrial physician. If sick at home he has the care of the visiting nurse and the social worker. His future is provided for by his industrial insurance and old age pension. In his declining years he enters some rest home for the aged. His dying pillow is smoothed by the institution nurse and his room brightened by the home visitor. Some burial society looks after his funeral. At last he lies at rest after a long and pleasant journey along the free health road. A high ideal to strive for, and a pleasant journey,—we wish him well!

Divergence of Interests

This subject of the relationship between the health department and the physician can be discussed from two diametrically opposite points of view, both of them true enough so far as they go, but neither giving a fair all-around picture.

One method is to bring out the fact already sketched in outline that modern health departments may be said to represent the aspirations of the physician for greater service to his fellow man; to rest our case upon the vigorous support given in early years by the medical profession and to recall that they have been developed by members of the medical profession to a far greater degree than by any

other professional or social group.

This method might be suited to after dinner speaking before medical societies, but would fail to even hint at the serious questions of mutual adjustment which health departments and practitioners of medicine are now facing.

Another way of treating this topic is to dwell upon the growing divergence in points of view of the practitioner of medicine and the health administrator in their fundamental conception of what the functions of health departments are. That this divergence of view exists, is growing, and is yearly becoming a more and more delicate point cannot be denied.

This divergence of interest, viewpoint, ideals and objectives, between health departments and private practitioners of medicine is largely unnecessary; largely a result of mutual misunderstanding of terms, and is to no small extent the result of application of foreign terms to American conditions with no real basis in fact.

That this non-cooperative attitude of doctors, due to their feeling of suspicion as to the ultimate objectives of health administrators, is more apt to injure the standing of the profession with the public than it is to permanently block the adoption and development of the particular proposals to which the doctors object. However, although the situation is serious, matters have not yet gone so far in this country as to produce an actual lining up of health departmental officials and practising physicians as definite antagonists, although this point is almost reached every year now in our legislative halls apropos of some public health measure. Also, full and frank discussion of all sides and angles of the questions of public health and social medicine ought to be the constant policy of every organized medical club, the district or county medical societies and the state and national medical associations for many years to come, if the medical profession is to emerge with credit from this process through which we are now passing of gradual transformation of our machinery for combating disease and human defects, whether physical or mental.

One thing is certain—the medical profession cannot dodge this issue. It is upon us; the tendency of the times insists upon a more adequate, more anticipatory and more widespread system of combating and conquering these maladies that human flesh is heir to than has ever before

been the case. If we as physicians do not respond to this demand public opinion will gradually develop a new type of profession that will.

Preventive Medicine Inevitable

Assuming that the medical profession as now constituted is to endure in recognizable form, its function must change more and more to the practice of preventive medicine, to the supervision of well people, and it must become less and less the group to be called upon only in times of emergency and distress due to temporary or permanent, partial or complete breakdown of physiological or mental functions.

To state this in another way, whether they like it or not, whether they consciously analyze it or not, all physicians are now becoming, and in a much more pronounced fashion in the immediate future will continue to become, practitioners of preventive medicine, or, in other words will have to take on privately many functions health departments now do publicly.

The real question is—what road shall the profession travel in reaching this destination?

Broadly speaking, there are only two possible ways opening before us. Neither are as yet broad roads; both are full of obstacles, rough places, blind forks, and very dimly indicated. Yet if our profession is to endure in a form as recognizable compared with its present form we must in the next half century, possibly sooner, go through by one road or the other and arrive in the land of real preventive medicine. I am postulating now preventive medicine by all physicians as an everyday practice for the benefit of all their fellow citizens all the time—not preventive medicine in the narrow and restricted sense in which we use the term today as describing the functions of health departments.

One of these roads I will call state medicine. Personally I strongly hope that we as American physicians will never have to travel this road, but I often fear it may be our ultimate destiny as a profession. By this term I mean a type of procedure which is *not* being carried out, *not* being consciously striven for by health departments of this country, but a type of procedure which has been definitely accepted as a nation-wide professional and governmental policy by several European countries. It has been the basis for much of the agitation against the present activities of American health departments by a certain element in the medical profession of this country.

I wish to make clear now my feeling of antipathy to this ideal. It is not based on worry over the future of American physicians nor any objection *per se* to the thing being attacked as paternalistic, socialistic, etc. It is simply because I am beginning to feel more and more doubt as to the soundness of any such conception. I am afraid it will turn out a gold brick, which will not do what its proponents claim for it.

The other road is the one forecasted to considerable degree by Sir James MacKenzie in his book, "The Future of Medicine."

This road involves a considerable extension of the health department's field of action but contemplates a final cooperative attitude on the part of the health department and the private physician to a degree nowhere approached today, and at the same time avoids the final domination and practical absorption of the practitioner by the Health Department.

Concepts They Carry

It is necessary to state that there exists no definite authority for the use of the terms state medicine and preventive medicine in the sense in which I am about to use them. Nevertheless I think I am distinguishing between them in a fashion that most American sanitarians will roughly agree to—viz.: that by state medicine we include the definite invasion of the field of curative medicine by the state, including a certain degree of supervision of the private practitioner of medicine and a certain guarantee of his remuneration directly by the State.

It is the corollary of this definition that preventive medicine includes all manner of activities that bear upon the prevention of disease or promotion of better health and vigor, but does not include the idea of cure, and that there are many important differentiations that are properly to be retained between the idea of cure and the idea of prevention.

It must be conceded promptly and fully that there are many twilight zones in the respective fields of curative and preventive medicine, and it is extremely difficult for any of us to draw the line sharply. For instance, the provision of venereal disease clinics where not only diagnosis is made but treatment administered is clearly an invasion of the field of "cure" on the part of the public health administrative organization, but the important part in prevention of further transmission of communicable disease that such curative treatments plays is so well recognized that only

the most violent of the *laissez faire* type of medical mind objects to the encouragement, introduction and financial assistance of such clinics by public health administrative agencies.

In a similar fashion the question has been forcibly brought to the front in many states in recent years whether the scarcity or absence of medical practitioners in many rural sections is not of itself a public health problem of serious magnitude and hence a primary field for activity on the part of health departments.

Making all due allowances for the folly of any one individual attempting to speak for even all of his own limited group and urging you to refrain from considering the distinction now arbitrarily drawn for the purposes of this hour as a general or accepted distinction, I will from now on use state medicine as a very broad term including all that is generally understood to be involved in public health work as we commonly use the term plus a fairly definite inclusion of some of the activities of curative medicine as well and preventive medicine as a term in which curative medicine is considered as beyond the scope of the jurisdiction of government.

Not many years ago we used to endeavor to further distinguish between preventive and curative medicine by insisting that preventive medicine or hygiene was concerned solely with people in the mass and not with the individual at all. As long as public hygiene concerned itself almost exclusively with the negative concept of health, the concept of dodging infection, this distinction was much easier to make than today when the duty of the state to reinforce the vitality of its citizens by all measures that will better promote the positive side of health is quite generally acquiesced in by our citizens except by a numerically small but vocally conspicuous group.

The fields of infant hygiene, nutrition work, dental hygiene and physical education are certainly matters which finally depend upon the individual rather than the mass route of approach yet who would deny their place today in the proper field of activity of the official health departments?

I will go one step further and assert that the concept of state medicine, as a method of social organization or of governmental activity covering everything relating to health and disease is essentially a European concept which—(Continued on page 848)

No Maudlin Sympathy Invalidates the Rigorous Program
of Physical and Mental Reconstruction*

THE reclamation of delinquent girls is wholly a matter of education. If the reciprocal responsibilities of community life can be maintained for a period sufficiently long to inculcate the desire for improved conditions along with the habit, then one of the most difficult problems of education faced by a commonwealth is solved. The Indiana plan has been so successful over a period of many years as to command interested examination.

The Indiana School for Girls at Indianapolis is an ideal plant for an educational experiment. It has the advantage of close proximity to a large city, but the detachment of its elevated site suggests entire separation from the complexity of life that has been the undoing of the entrants of this school. Six buildings, each a complete unit, with fine outlook, provide an adequate basis of operation, and their size is not so great but that the school can be operated on the cottage plan, preserving family relationships, while the educational work—academic and technical—creates such inter-cottage activities as make for social adjustment and community of interests. Under these circumstances the transformation of the ineffectual, introverted delinquent into an active, interested, even happy individual seems less a miracle than a thought-out plan.

For failure is only another term for misdirected energies and the fact that a correctional school for girls is necessary anywhere is not so much individual failure on the part of the girls themselves as failure on the part of society to give them a place in the sun. They represent first the failure of the home, or they would have responded to the saving grace of home nurture; of the church, or some lingering touch of an ideal would have en-

abled them to avoid social stigma; and of the school, or they would have learned long since the futility of social behavior.

The girl who "just grows" does not learn from experience; at least she cannot be said to gain much useful knowledge from a harsh, resisting environment during her plastic years and if an early emotional set further complicates her adjustment in a world

sence necessitate failure; hence the general inadequacy of social machinery to develop persons of this type along useful lines is the more incriminating.

The really serious phase of this question is the vicious circle of one failure engendering another. Among these delinquent girls, the breaking of the home is the one constant factor in practically all cases. More than 75

per cent of the inmates of the Indiana School for Girls come from homes that are disrupted; more than 50 per cent are the children of divorced parents. How can a child's mind become integrated when thirteen makeshift provisions for a home are made over a period of two years, as were recorded in the history of a child recently committed to this institution?

The state which through its divorce courts frees parents from responsibilities to one another is called upon sooner or later to assume in some degree responsibility for the children who are turned adrift. For the child "must belong" if it is ever to find itself as a well ordered personality. How otherwise is the "I" and "my" feeling of sharp antagonism toward an unfeeling world going to get itself transformed into the "we" and "our" of cooperative effort?

Dr. Session's Method

Dr. Kenosha Sessions, superintendent of the Indiana School for Girls, is a psychologist first. Through skilled tact she is able at once to ascertain what materials are left of the wrecked personalities she is dealing with, and then she proceeds to build character. She is a broad humanitarian afterward. With her soul sickened by the spectacle of the needless suffering of these girls, nevertheless she coolly and consistently ap-

Social Failure and Delinquency

THE home has failed these girls committed to the Indiana School for Girls; 75 per cent of them are recruited from broken homes; 50 per cent from homes where parents are divorced.

The school has failed them. Either as wanderers, repeaters, or recalcitrants, they have been unable to receive their quota of academic and social training, and hence remain misfits.

But the State through special educational method compensates for earlier shortcomings, and returns as useful citizens more than 70 per cent of all such wards committed to its care.

too complex for her mental equipment, the situation becomes hopeless without special measures for its relief. And these children are inadequate. Of all girls committed during the past two years, less than one-third showed a mental rating above 70. But mental ineptitude is no bar to social usefulness and the joys of reciprocal relationships. So many of the necessary tasks of life are routine procedures that a satisfactory status is maintained throughout their whole careers by many persons of subnormal minds. Great versatility and high intelligence quotients do not guarantee an even tenor of life, nor their ab-

Girls' assembly room in one of the cottages. Every effort is made to free the place of institutional atmosphere and to surround the girls with such influences as are conducive to joyous, wholesome living.

A corner of one of the girls' dining rooms, typical of the rest. The most particular care is given to every detail of appointment and service, for which the girls themselves are responsible.

plies the insight and corrective method perfected in her years of experience with the insane. Insanity, of course, is different only in degree. These girls with false objectives, wrecked hopes, self-pitying attitudes, and fixed resistances are often a much more complex problem than frank insanity.

Moreover, in spite of their resistances, they become willing to be cured. Dr. Sessions receives personally every girl committed to her care. Incidental to an interview, made as informal as possible, the girl is induced to tell her whole story and, what is quite fundamental, she is brought to free admission that, however great her wrongs, she herself is the chief offender. No subterfuge, no cowardly cringing from the logical consequences of her course is allowed to modify the wholesome effect of a frank facing of facts. Once her soul is unburdened, she is free to reconstruct her life.

The first day in the institution marks the beginning of a new era for the committed girl. Every girl enters the school through the hospital. There is no resident physician, but the nurse in attendance sees that the new entrant is suitably bathed, shampooed and prepared for the thorough physical examination she receives at the hands of the physician on the day of his next regular visit to the institution. He comes three days a week. The interval

of isolation and complete rest gives the girl ample time for reflection. She has been made to feel that the dead past is buried, that opportunity opens, and that she will be there no longer than her own acceptance of the situation and performance of duty and training make necessary. The whole scheme gives incentive to the helpless and baffled spirit she brought with her.

The physical examination is real. It involves weighing, measuring, history taking, laboratory investigation, mental tests—all that is required for the proper understanding of capacities and handicaps, for proper placement, and for intelligent management. The girls are usually pallid and undernourished. It is the rule to encounter decayed teeth, bad tonsils and other neglected conditions. Venereal disease exists in about 30 per cent of all admissions. A rather remarkable series

of cardiacs marked the last hundred admissions, but quite as remarkable is the lack of inconvenience here even from heart handicap under a medical system that removes focal infection and makes assignment according to physical requirements. An adequate dietary, sufficient rest, and a proper balance between interesting tasks and refreshing play do the rest.

This does not mean that any namby-pamby sentimentalism governs the routine. The school course involves real work of a nature that disciplines while it trains vocationally and mentally according to the needs of the student. Precision of method and perfection of output are uniformly required. The girls work hard, but they have their reward. Usually they experience here their first joy of performance, and whatever they do, whether laundry or garden work, cooking or sewing, nothing short of the best they are individually capable of doing is accepted, or considered acceptable. Paradoxical as it may seem, the girls are fondest of the most exacting taskmaster. They demand fair play, but scorn favoritism; they regard it a special privilege to serve the house officers and their guests, and the beauty of their work begets in the interviewer the earnest wish that other children presumably under more favorable conditions might somehow be

vouchsafed the privilege of similar training.

Primitive Means Unnecessary

Almost no disciplinary measures are necessary. A detention cottage is provided, but it is mostly untenanted and the really incorrigible subjects have usually been regarded as custodial cases on the basis of low mental rating or emotional instability. Discipline is administered chiefly through reduction of status. Pride of place ranks with pride of performance in social incentive.

The school is actually an educational institution. The girls are consigned here to learn how to live. When they learn, and it is considered that habit is sufficiently established to enable them to go safely, they are put out in homes or workshops as wards of the state until they reach the age of twenty-one. The wages they earn are subject to strict accounting by the girls themselves, and the margin above what is considered reasonable expense is held to their credit and turned over when they are finally released. Interesting variations are noted in the use they make of these funds upon release, but that is another story. A state agent, Miss Nan B. Wood, surveys the homes where the paroled girls are placed, and acts as their adviser until they are legally free. That the system is successful is proved by the fact that very seldom are paroled girls recommitted.

The successful educational effort at

lar classes, individual diagnosis and adapted treatment get her to growing satisfactorily elsewhere. Special education is expensive, but it is not deliberately wasteful of human material

ests of others thwart her wishes. (2) Obedience she must learn if she is to profit by the experience—individual and social—of others and avoid the painful effects of reacting only

or certainly potential of the dangers that attach to neglect of these problems. But the system as carried out at the Indiana School for Girls is not merely a corrective method. It is a theory of education much broader than a program for delinquents. Three things the child must learn, according to Dr. Sessions, if she is to fit comfortably into the social pat-

tern on the basis of her own desires. (3) Respect for the rights of property ownership if she is not to become a predatory animal instead of a mutual sharer in community interests.

In at least three children, normal in every way and surrounded by family influences, the same methods of training have been equally successful. One of these, a girl who had more money than one person can well use, but whose parents loved her well enough to train her well, was supervised throughout her early years by Dr. Sessions; another, a boy, whose parents were poor and who had to work his own way through college; and the other, the child of well-bred parents, determined to do their best for their son. All of the three are healthy, self-reliant, successful, and happy individuals under widely different circumstances. And, what seems somewhat significant in view of the similarity of their educational tutelage, it is said they all look alike!

Italy Establishes Eight Hour Law

A legislative decree of March 15, 1923, establishes an eight hour day and a forty-eight hour week of actual work in industrial and commercial establishments, offices, public works, and hospitals in Italy. The decree does not apply to domestic service, and the application to agriculture is to be determined by further regulations.

The girls are trained for leisure as well as for work. Each cottage is provided with assembly rooms and abundant opportunity to cultivate some of the amenities of life which have hitherto been wanting in the lives of these girls.

the Indiana girls' school is the best sort of argument for special education for neglected groups everywhere. When a pupil cannot progress in regu-

tern: (1) Self-control she must have if she is not to spend herself in futile petulance when material things are denied her and the conflicting inter-

The Day Nursery As a Child Welfare Agency

Organized As a Connecting Social Link Between the Unbroken Home and the Foster Home. The Day Nursery Is a Home-Conserving Agency

BY FRANCES COLBOURNE, EXECUTIVE SECRETARY, PHILADELPHIA ASSOCIATION OF DAY NURSERIES, PHILADELPHIA, Pa.

IN spite of the fact that the day nursery idea originated in Europe more than one hundred and forty years ago, and that day nurseries have been in existence in America for nearly half that period, their claim to a place in the front ranks of child welfare agencies is of more or less recent development. Out of the total of six hundred nurseries known to exist in the United States, sixty odd are located in Pennsylvania. Of these, forty are in the city of Philadelphia, serving—at a rough estimate—an average of from eighteen hundred to two thousand children per day throughout the year. This is certainly a large enough group to attract the attention of thoughtful citizens and to arouse the question, Why is this form of child welfare needed and how does it meet its responsibilities?

The passing years but emphasize more clearly the child's need for normal family life. The day nursery is not a makeshift to be utilized by the woman who merely prefers industrial or other occupation to her maternal responsibilities. It recognizes that the mother of very young children and the mother of a large family should not be in industry; it is not a futile substitute for the agency which is unprepared to meet the financial relief incident to a constructive plan for rehabilitation, although, under given circumstances, and as part of an approved plan, it works hand in hand with the family welfare agency and the Mothers' Assistance Fund.

It is vitally interested in the prevention of industrial accidents and the bettering of laws affecting deser-

tion and non-support; in programs for minimum wage, health insurance and maternity benefits. Until these and other social forces are better equipped to meet the situation, however, it has a definite field to cover.

The day nursery may be called a connecting link between the home intact—that is, the unbroken home, or

into industry, no effort at meeting the crisis which is making her the breadwinner instead of the homemaker, we are open to grave suspicion. We cannot isolate the child from his environment: any plan for him affects the whole family of which he is a member, and in turn affects the community welfare, with danger

of setting loose myriad forces we are later unable to control. We dare not build lightly or unintelligently. A prompt investigation of applications, with a home visit before admission, is the only safeguard. The mother's problem must be discussed from every angle—financial pressure, emergent though it be, must not be the dominant factor, but part of a carefully gathered mass of data which will present the whole, true picture of the situation. Plans must be made by someone who knows the resources of the city and whose training and ex-

A photograph of sleeping children in the Jane D. Kent Day Nursery, Philadelphia.

the broken home, where the mother receives a pension which enables her to remain with her children—and the foster home. Properly organized, it is a home-conserving agency, making it possible for the mother upon whom is placed the burden of the wage-earner to meet this responsibility and yet keep her children under her own care.

The first responsibility of the day nursery justifying its claim as a child welfare agency will therefore be expressed in terms of admission standards. It is a very serious accusation that a nursery is one of the forces helping to destroy, rather than to build up the home. Yet wherever there is no intelligent study of the problem which is sending the mother

perience can suggest not only the best solution for the present emergency, but whose vision can map out the course which will look toward the re-establishment of the normal home at the earliest opportunity. This is often a long and strenuous task. It cannot be accomplished from inside the nursery; it means friendly contact with and intimate knowledge of the family in the home.

Each nursery family is a new investment—an investment of time, money, and limitless energy. The wise nursery will employ a trained social visitor, not only to "look into" the investment before taking it on, but also to ensure the highest returns—a maximum of profit with a mini-

mum of loss—after the investment is entered into.

Satisfied that, under given circumstances, day nursery care is the best solution, we can turn our attention to a brief survey of the outstanding service to be offered there. The pre-school child and the kindergartner, who make up the large majority of nursery population, cover the universally acceptable age for preventive care. We are constantly reminded by the doctors that this is the period at which occur the greatest number of contagious diseases—now largely preventable—by psychologists and educational authorities that it is the formative period of life. The responsibility of the day nursery, with its opportunities for developing and fostering physical, mental and social health, is almost staggering. The second step is obvious: medical examination of each child, before admission—as a safeguard from contagious contact, with further examination for a complete knowledge of the child's physical condition, at the earliest possible date. Furthermore, the opportunities for preventive care cannot be lightly neglected or ignored. The progressive nursery calls for a complete and recorded examination by an interested and efficient doctor, with regular weekly visits to the nursery for the purpose of follow-up care, and re-examination of every child at stated intervals. The pioneer nursery of today includes a psychometric examination, and adds physical examination of all other members of the family, not excluding parents, to which the day nursery ward belongs. The mere finding of defects is, of course valueless. The social visitor will see that the doctor's recommendations are carried out, through the use of clinics and hospitals, will persuade and educate the ignorant mother, arrange for operations after consent has been obtained, secure convalescent care and insure proper food and hygiene in the home.

So much for medical preventive measures. In the nursery itself, the fundamental responsibility as a child welfare agency will be expressed in terms of a competent person in charge of the day nursery, with a sufficient staff of workers. The fostering of an atmosphere in which the child may grow mentally, as well as physically, is one of the most neglected and delicate adjustments which the nursery can make. Temperament can be made or marred—personality developed freely and fairly, or dwarfed to suit the old limits of conventional

adult morality. The plastic mould is here in the making—and it cannot be successfully done with clumsy, ill-adapted hands and poor, outworn tools. The superintendent must have something beyond a "natural love of children"; she must know something of the psychology of childhood, of the value of play, to add to her qualifications as a "good housekeeper" or thrifty manager. Her share of the nursery's responsibilities is no light one and she must be aided by a sufficient and efficient staff, and must have at her command, besides, the equipment needed to carry out a healthy, daily routine in the nursery.

Equipment to include: (a) Cribs provided for children under 3 years of age, a separate crib to each child. (b) A rest room, with from one to two hours' rest, provided for all children between 3 and 6 years of age. (c) An isolation room for cases of suspicious contagion. (d) Modern toilet conveniences with separate toilets for boys and girls. (e) Separate towels, wash cloths, combs for each child, with supervision in the wash-room. (f) Nursery aprons for all children; infants should be dressed in nursery clothes. Walls and floors should be washable.

No modern child welfare program is complete without due consideration of nutritional needs and the nursery superintendent must be allowed a budget which will permit her to provide at least two meals daily, one of which shall be a midday dinner of suitable diet, while a generous, and even lavish supply of milk will be an investment yielding 100 per cent dividends in "Children Preferred."

Lastly, it is the responsibility of all child welfare agencies to "give an account of their works." Surely the minimum requirements here will be a record for each child, containing at least the name, address, occupation, wages, and place of work of parent or parents; names and ages of other children, and reason of admission to nursery. The progressive day nursery will not rest satisfied merely to add to the physical and social health of its own limited population. The information that can be gathered by the social visitor can be of infinite value in adding to general knowledge which may lead to social improvement on a wider scale. There will be health records of medical value, social data of interest to other welfare agencies, statistics which will swell the evidence of need for industrial legislation. In short if we believe in the child's right to home life, we cannot

be content to receive the "effects" without trying to understand, possibly ameliorate the fundamental "causes" which send the mother into industry and make the day nursery a necessary part-time substitute for the home.

Ellis Island Needs More Room

Recommendation made to the Department of Labor and Treasury Department by Assistant Secretary Wadsworth after an investigation of conditions at Ellis Island includes a request for funds to establish new buildings with the purpose of providing the United States Public Health Service adequate space for its needs. Of the two thousand aliens which are now permitted to land each day at Ellis Island, from six hundred to eight hundred are given intensive medical examination. Special committees are provided for men and women. Five women doctors are employed for this purpose. The space available, according to Dr. Wadsworth, makes eight hundred the maximum number who can be handled in this way. The balance of the aliens, from 1,200 to 1,400, are inspected as they pass out of the waiting room, each one by two doctors. More space and a carefully arranged system would provide for intensive examination of two thousand, as all should be subjected to the same discriminating physical tests.

It is suggested that the demand for hospitalization could well be reduced by a more careful examination of immigrants before they are taken on board, but the report concerns itself chiefly with the improvement that can readily be introduced if additional space is made available for the public health service.

Award for Contraction of Disease from Furs

The London County Court recently rendered a verdict for damages in favor of a woman who claimed that she had contracted "fur dermatitis" from the collar of a coat she had purchased from a customer. King's College Hospital reports between thirty and forty cases, all due to wearing cheap furs.

An analytical chemist, called in for the defense testified that the disease was caused by insufficient washing after dyeing the skins and that it was only the Belgian and German dyed skins that were found to be infected, the ones imported from America did not show any defects.

The Subnormal and Psychopathic Child Is a New Method of Attack

Abnormal Reaction to Unfavorable Environment Does Not Preclude the Capacity to Respond to Changed Conditions

BY LOUIS A. LURIE, M.A., M.D., CINCINNATI, OHIO.

IN STUDYING the problem of the subnormal and psychopathic child we must perforce concern ourselves entirely with the study of conduct reactions. For after all, psychiatry in the broadest sense, can be defined as the study of the conduct reaction of the individual in his attempted adjustment to his environment. Conduct reactions in turn are dependent upon two factors, namely, the innate physical and mental capacity of the individual for reacting and the nature of his environment. Obviously, to evaluate the first factor a thorough physical and neuro-psychiatric examination is necessary. As far as the second factor is concerned the mere knowledge of the abnormal environmental influences entering in any given problem case is not sufficient. It is essential to know in addition the conduct reaction of the particular child when removed from pernicious environmental influences and permitted to live in a normal environment.

It is just such a complete study that we are making at the Psychopathic Institute of the Jewish Hospital. Here we have created an observation station where the child's social reactions in a normal environment can be observed with the same scientific precision as is applied in examining his physical condition. The Institute is housed in a private dwelling on the grounds of the Jewish Hospital and its capacity has been purposely limited to twelve, in order that the child might be impressed with the fact that he is living in a home, rather than in an institution. The entire scheme of the furnishings further accentuates the home-like atmosphere which is so essential.

Before being admitted to the Institute the child is placed in the children's ward of the Jewish Hospital where certain routine examinations

are made. These include a physical, neuropsychiatric, visual, dental, x-ray and serologic examination. Special examinations are made by members of the staff of the hospital as the indications arise. In this way the child receives the benefit of diagnostic group medicine. Upon completion of these examinations the patient is transferred to the Institute. Here the child becomes a member of a

the child. The defective and retarded child who probably has become discouraged through inability to cope with the more or less abstract work of the regular school curriculum, rejoices in his ability to perform manual tasks and to accomplish definite results. Self-esteem is thus unconsciously engendered, and a wholesome mental attitude created.

Many of these children, as a result of constant failure either at school or in industry, have developed an inferiority complex by the time they are sent to the Psychopathic Institute. This must be overcome before any permanent adjustment can be made. Nothing is more conducive to effort than the knowledge that one has the ability to accomplish or produce. At the same time the method and character of the child's responses disclose his potentiality for future industrial training and for social adjustment when returned to the world.

Recreation and comfort are not overlooked. Various forms of entertainment provided by volunteer social workers—outings, club activities, theater parties and athletics—also present opportunities to observe the child while at play. The effects of a clean home, clean beds and clean living in general are noted. All reactions are carefully recorded on special charts, and finally correlated with the facts obtained from the physical and mental examinations. These comprehensive data serve as a basis for diagnosis and plan of treatment.

The following case reports will illustrate the results of such procedure.

Case 1.—A. T., a boy, age 9, was referred to the Psychopathic Institute of the Jewish Hospital by the Juvenile court of Hamilton County.

Chief Complaint.—The complaints registered against the child were stealing, running away from home

A Medico-Social Experiment

FEEBLEMINDEDNESS should not be considered a clinical entity.

Rather it should be looked upon as a symptom of some grave, underlying constitutional disturbance, the correction of which will very often lead to a marked improvement of mental state, if not to a complete cure.

The enormous possibilities of this concept in the handling of a medico-social problem that has been looked upon as hopeless brings out the importance of the experiment being conducted at the Psychopathic Institute described.

family and as such is called upon to share in its routine life. To the boys are assigned such tasks as keeping the lawn and yard in good condition, taking care of the furnace, painting and doing whatever repair work they are capable of doing. The girls help wash dishes, make beds, prepare meals, sew, and mend. Those of school age are sent to the district school. Definite time is set aside for study and a teacher is provided for those requiring special instruction.

Several afternoons a week are devoted to vocational training in the form of bead stringing, sewing, carpentry, weaving, pottery, and reed work. These occupations are of direct benefit to the patient and of great importance to those observing

A detached house, utilized as the home of the Psychopathic Institute, preserves the atmosphere of home life.

and general incorrigibility. At one time he was implicated in a sodomy case.

Onset.—According to the mother, the boy began to be incorrigible a year previous to his admission to the Institute, when she was forced to go to work in order to help out the family budget. The boy was thus left to his own devices and unfortunately became associated with a group of incorrigible boys, two of whom already had court records.

Family History.—Maternal grandmother insane; mother very nervous; father was a delinquent, and is a graduate of the Lancaster, Ohio, Reformatory. The family situation is a very bad one, the father has been working only part time; the mother has been away from home the greater part of the time doing washing and cleaning.

Past History.—The personal history is negative except for the fact that at the age of seven the child received a severe injury to the right side of the skull, since which time he has suffered from night terrors.

Examination.—The general physical examination was negative. The child has the saddle shaped nose and characteristic wrinkling of the skin around the angles of the mouth so often seen in congenital lues. The neurologic examination showed that the patellar reflex was absent on the right side; both achilles reflexes were also absent. An x-ray of the skull showed a thickening of the frontal bone over the right supraorbital region.

The blood Wassermann and Hecht Gradwohl tests were four plus positive. On the Stanford revision of the Simon Binet tests, the boy received an intelligent quotient of 88. Mentally he was retarded one year and two months.

Mental Makeup.—Temperamentally he was suspicious, sanguine, impulsive, non-egocentric and generous. He exhibited a violent temper and was

very obstinate and intellectually dishonest. Mentally, however, he was very alert and emotionally highly unstable.

Social Reaction.—The first thing the patient did upon admission to the Institute was to attempt to run away. Several of the other boys caught him and brought him back screaming and fighting. After this outburst of temper, he became more cooperative and adjusted himself fairly well to his surroundings. He became less suspicious and impulsive and more tractable. He remained, however, emotionally unstable. In addition he showed the lack of proper home training, his general deportment being rude and ill-mannered.

Diagnosis.—(1) Congenital neuro-syphilis.

(2) Emotional Instability.

(3) Lack of proper home and environmental influence.

Recommendations.—(1) Intensive antisyphilitic treatment with the hope of relieving his emotional instability as well.

(2) Social rehabilitation of the home; if that is found impossible, child should be placed in a boarding home.

Course.—Both recommendations have been carried out with the result that one year after the patient was discharged from the Institute the report of the Juvenile Court officials is that he is getting along nicely both at school and at home. The boy reports regularly at the Institute of his own accord.

This child represents a type that is fairly common; a type in which the abnormal conduct reactions are due

both to physical and environmental influences. Furthermore, unless both factors are recognized and treated we cannot hope for a permanent adjustment. In this particular case the emotional instability no doubt was due to the possession of a nervous system vitiated by hereditary syphilis. The emotional instability in turn permitted the environmental condition to exert a pernicious influence thereby producing a delinquent and incorrigible child. The solution of this problem called for the correction of all three factors.

Case II.—L. C. a girl, age sixteen, was admitted to the Psychopathic Institute at the request of several social agencies, as well as of the Juvenile Court.

Chief Complaint.—The girl was said to be feeble minded and a sex delinquent. The diagnosis of feeble minded-

ness been made as a result of several psychometric examinations. Her intelligence quotient ranged from 68 to 70.

Examination.—The general physical and neurologic examinations were negative. A visual examination, however, showed that the girl was suffering from chronic trachoma and that her vision even with glasses could only be brought up to half normal.

The girl's mental makeup was very interesting. She was very suspicious and untruthful. Her manner was very impertinent and although willing to work she was not dependable, requiring much supervision and correction. An outstanding characteristic was a high degree of suggestibility. Her conduct therefore was determined by the individual from whom she received a suggestion. In addition, the girl was very moody. During the moods she was sullen, lazy, and impertinent. The patient herself accounted for these moods by physical complaints. However, this could never be definitely established as many thorough physical examinations failed to reveal any cause for the supposed pain.

Little by little, the environmental influences of the Psychopathic Institute began to have effect and the girl began to improve both physically and mentally. She was made to assume responsibilities and from the moment she did, there was a continuous improvement in her conduct.

The social history in this case is very bad. The report showed that the home is in a wretched condition. The mother is feeble minded. Two brothers are also feeble minded and one sister is suffering from hysteria. The parents are absolutely unable to care for their children.

Diagnosis.—The following diagnosis was made: Patient is mentally retarded. The mental retardation is

As soon as possible the children under observation are given such routine responsibilities as they would have in a family unit.

The children are observed at work as well as at play and full opportunity given for satisfactory adjustment.

due largely to a severe grade of defective vision. The delinquency and character defects are due to lack of proper home influence.

Recommendation.—(1) Medical treatment for the eyes. (2) Girl should be removed from her home and placed in a boarding home under strict supervision.

Course.—The girl expressed a preference for work in a hospital. This was secured and she has worked steadily in a hospital for more than a year. She is very happy in her new surroundings and is working faithfully and diligently. Her superiors are pleased with her efforts.

This case illustrates the fallacy of diagnosing feeble-mindedness as a result of psychometric tests alone. Had this girl not received the benefit of a thorough medical examination and social observation at the Psychopathic Institute she would no doubt have been committed to the state institution for defective delinquents. In fact, such a recommendation had already been made before the child was referred to the Psychopathic Institute.

Case III.—H. U. was referred for examination because of lack of mental development. Although eight years of age, the child could neither read or write and was able to pronounce but one word "mamma." Furthermore she was unable to dress or undress herself. Physically she appeared to be a perfectly healthy child, being fat and rosy checked.

The family history was negative. The child had an uneventful infancy. She had her first teeth at twelve months and walked at fourteen months. During past six months the child gained enormously in weight.

Her mental retardation became noticeable at the age of two and one-half years.

With the exception of a decided convergent strabismus, the general physical and neurologic examinations were negative. There was, however, a marked endocrinopathic state. The child was very obese, being about thirty-five pounds overweight. There were large deposits of fat over the breasts, abdomen and hips. The skin was soft and smooth. The presence of vasomotor disturbances was evidenced by the mottling of the skin and the cold, moist and cyanotic extremities. The face was broad and of the acromegalic type; the teeth were notched and spaced; the thyroid gland was palpable but not enlarged. The fingers were typical of dyspituitarism being short and spade shaped.

X-ray of the skull showed a large and shallow sella-turcica.

The blood Wassermann of the child as well as of the parents was negative.

Mentally the child appeared to be about four years of age, although this could not be determined accurately as it was very difficult to fix the child's attention during the psychologic examination.

A diagnosis of dystrophy adiposogenitalis associated with mental retardation was made. The patient was given extract of the whole pituitary gland combined with extract of the thyroid gland in gradually increasing doses.

It was not long before the improvement was noted, two months after beginning the treatment the motor restlessness was greatly reduced. The face assumed a more animated expression and the child was using many words. Four months later, the child was able to recite the entire alphabet and was able to have her eyes tested for glasses by means of the regular chart.

In addition she had learned to dress and undress herself and wash, dry and stack dishes. In less than a year she was able to speak well and take part in the general conversation.

Today she speaks well, reads and writes and is able to add three columns of figures. Her general deportment is that of a normal child.

Constitutional Causes

This case as well as the preceding one, should make us view the problem of feeble mindedness from an entirely different angle. We should disabuse our minds of the belief that feeble mindedness is a clinical entity, diagnosable means of a psychometric ex-

amination, and realize that it is merely a symptom of some underlying constitutional disturbance which very often is remediable. Such an attitude will permit the substitution of a constructive program in place of the present palliative program of building more and more custodial institutions.

We have already made a small beginning along these lines in Cincinnati where we have established an institution known as the Home School. Here we have placed a number of definitely feeble minded children who have been thoroughly studied at the Psychopathic Institute of the Jewish Hospital and who as a result of that study show that their feeble mindedness is associated with some physical condition that can be corrected by the exhibition of the proper therapeutic measures. These children will be kept at the Home School for a period of years and given intensive social and vocational training, and proper medical treatment in the hope that thereby their mental condition will be so improved that they will be able to take their place in society as self-supporting individuals.

Up to the present time we have studied more than one hundred fifty children who have been conveniently divided into two large groups, namely, functional and organic. Numerically the cases are almost equally divided between the two groups.

In the functional group we have placed those children who are normal

The place bears very little resemblance to a custodial institution. In fact, it is designed to discriminate between the curable and incurable cases.

physically but who present conduct disorders. This group contains the neurotic children, the emotionally unstable, the hyperactive types, and those suffering from pernicious environmental influences. This grouping permits of a further subdivision into (a) the environmental and (b) the individual.

In the first subdivision—the environmental—belong those problem cases where the abnormal conduct reactions are due primarily to influences external to the child, while in the second subdivision—the individual—belong those cases in which the abnormal conduct reactions are due to functional disturbances within the child himself. It is in this group especially that the tactful psychiatric social worker is of the greatest help. Here also the quickest and most startling results may be expected.

In the second, or organic group, are placed the children who show some form of psychopathy as a result of an organic lesion.

As is to be expected, lesions of the central nervous system are the most numerous and of these syphilis of the nervous system constitute nearly 50 per cent.

Next in frequency to involvement of the nervous system come disturbances of the endocrine glands. A very large percentage of the organic cases have been improved through medical treatment.

In conclusion the author wishes to

emphasize two very important facts:

(1) The nature of a child's conduct reactions depends upon two factors, namely, his innate physical and mental capacity for reacting and the nature of his environment. Hence when confronted with any form of psychopathy in childhood both of these factors must be properly evaluated and the data thus obtained correlated in order to make a correct diagnosis and to outline the proper treatment. In addition, the reactions of the child when placed in a normal environment must also be known. At the Psychopathic Institute of the Jewish Hospital we have created an observation station where such a complete study can be carried out scientifically.

(2) Feeble mindedness should not be considered a clinical entity. Rather it should be looked upon as a symptom of some grave underlying constitutional disturbance, the correction of which will very often lead to a marked improvement of the mental state, if not to an entire cure. Such a thesis opens enormous possibilities for handling a problem that always has been and still is looked upon by many as hopeless.

Pride of place and pride of personal appearance contribute to the child's restoration.

To Rid the World of Leprosy

STRINGENT legislation, inhuman and one-sided, based upon the older conception of the leper as a total loss to society, an outcast and a pariah, while he perforce awaited the final horrid outcome of his disease, was none the less effectual in ridding certain European countries of the menace. Neglect of the problem prevents the United States from being free of the disease, although human conditions for the victim and the possibility of eventual cure make the problem far more promising of absolute control than it has ever been in the past.

More effectively than any other disease leprosy removes its victim from hope of social usefulness. He becomes a complete loss to society as worker with either hand or brain. Instead he is a costly menace. Hitherto deemed incurable—though not actually so—he has been a permanent charge upon society instead of a temporary care. The aggregate loss of earning capacity by the two million or more lepers in the world today and the cost of their care and mainten-

ance are a deliberate waste, as the disease is now quite possible of control within a reasonable time.

The problem, far less in magnitude than that involved in the control of tuberculosis, can by segregation and scientific care be reduced to insignificant proportions within a very short time. With no friendly refuge, the leper is hopeless. An investigation by the American Mission to Lepers is reported by W. M. Danner in the *Bulletin* of the Pan American Union.

Lepers are found all over the world, states the report. Russia probably has more lepers than any other European country. The Scandinavian peninsula is infected along its entire western coast line. Portions of Spain and Portugal are badly infected, and along the northwestern shores of the Mediterranean, lepers are found. India and southern China may be called hotbeds of leprosy. Japan, too, has many lepers. The Philippine Islands have about five thousand, greatly reduced from former numbers by segregation. The Hawaiian

Islands have a small quota. Practically the whole coast line of Africa is infected, in some sections heavily; also Madagascar.

Acting upon the advice of experts, the United States Senate Committee on Public Health and National Quarantine in 1916 presented the bill which became a statute appropriating \$250,000 for the purpose of providing a national leprosarium.

South America is by no means free from the contagion, which spreads up through Central America and into Mexico, where it is severe. Oceania and the islands of the seas have not escaped. Even far off Iceland has her leper colony and Greenland knows the disease. There are lepers in Canada and there are lepers in the United States of America. Certainly it is none too early to start an educational campaign in every nation where the disease exists.

The South American survey made by Dr. Browning is thought-arresting and gives opportunity for at least a limited study of the situation. It encourages—(Continued on page 830)

Editorials

IT IS not enough for the successful health officer to formulate a sound administrative program, to secure the financial support of the city fathers, and to obtain the active cooperation of the medical profession. These things he must do, but he must accomplish one thing more; he must develop an understanding of his program and a real participation in it on the part of the general public. This is the final and ultimate test of his capacity for leadership.

It is of no use to provide prenatal clinics and infant welfare clinics and tuberculosis clinics if the public do not come to them, return again to them, and carry back into their homes the instruction given. It is impossible even to gain an effective control over the common communicable diseases without a real comprehension on the part of the public of the principles involved, and a willingness to isolate a suspicious case "before the doctor comes." The public health objectives of twenty years ago could be attained by the exercise of police power. Those of today can only be reached by education, and again, education and still more education.

The public health nurse and the clinic doctor are of course the immediately effective agents in bringing hygienic knowledge to the individual. Yet after all they are but units in a larger organism. The health department as a whole must stand for something definite in the mind of the community if the nurse and the clinic doctor are to find a ready hearing. And, in this connection, when we speak of "the department" we could better write "the health officer"; for, as every student of education knows, the most effective publicity can only be secured when attention is concentrated upon a human personality. "The department of health announces so-and-so," or leaves one quite cold; but "Dr. Jones, the health officer, says such-and-such" may arouse a real interest.

There is perhaps no other member of the state or city government who, day in and day out, has such an opportunity as has the health officer to make a direct personal appeal to the people of his community. The power gained through the use of this opportunity has carried men to the highest

Leadership in Health Work

places of honor as in the case of the junior senator from the state of New York. It is a power which should be used by the health officer with a conscientious regard for scientific truth and a single minded devotion to the public service; but it is a power which should not be neglected. The ideal health officer is one who can so speak and write, so radiate the force of intellect and personality with tongue and pen, that his fellow citizens will regard him with respect and affection, and will be prepared to accept with confidence his leadership in the daily struggle with preventable disease.

IN THE name of athletics there has been created a system of interclass, interschool, and even international rivalry in games and physical prowess which raises the spirit of endeavor

Competition in School Health

among school children to a point not yet approached in any other line of their ambitions.

In a way the measure of success of competition in muscular coordination, team play, and personal excellence in athletics is in the number of original competitors and the quality and duration of the developmental period to which they are subject prior to the selection of the few who finally represent the many. And yet, with all the best of intentions, how small a portion of the boys and girls in school or college actually receive the full possible value of physical development when athletic competition is the desired end result, and how meager, how artificial, how limited within schools or classes are what stand for scholastic or academic competitions leading to the decoration and formal presentation of medals or bookish gifts at graduation time.

Have we not a greater game to propose? After all, the game of youth is life! Is there not a basis we can offer for contests within schools, or between student bodies of nations, where every child is a competitor and the time of the game is the whole school year, not a hectic ten seconds for a sprint or the steaming periods of a basket ball game?

A few scores could be proposed, easy of record, accurate and readily checked, involving the performance of teacher, parent, doctor, and nurse as well as school child, which should provide an all inclusive program in which every member of the community will have a stake.

These are the essentials of the score in such a school term game of health:

(1) The cleanest score in school attendance, *i. e.*, the lowest percentage of days lost from sickness out of the

total possible days of attendance of the school or class, or in military terms, the lowest non-effective rate.

(2) The best performance in remediable defects, *i. e.*, the lowest occurrence in class or school of correctable defects, including such defects as lack of immunity to small-pox or diphtheria.

(3) The nearest approach to universal compliance with a good standard of growth in height and weight for age during the school months.

(4) An acquisition of good posture in rest and in action.

It would not be difficult to set up a bogey score for the schools to aim at. We shall rarely find a day school in large cities where the percentage of absences falls below 4 per cent. In country boarding schools a record of only 1½ per cent days lost may be attained. Nothing but 100 per cent should satisfy perfection in scoring under 2, 3, and 4.

Already a series of cups have been offered in Yonkers, N. Y., for health competition on a somewhat similar basis, and the idea has even reached the select and conservative old line private and endowed boarding schools.

Who will be the first health officer or director of school health to promulgate the rules of such a competition, to issue a "Spaulding's guide," for its conduct? We suspect that if this were done few parents or school principals would be so dull as to miss the thrill of satisfaction in sharing with the child the happiness of being a member of the trophy school.

ONE of the outstanding events of the Boston meeting of the American Public Health Association was the report of the Committee on Municipal Health Department Practice. It will

Standardizing Health Practice

be recalled that this committee conducted in 1920 a survey of the health organizations of the eighty-three large cities in the United States.¹ The aim of the committee has been, first of all, to secure the establishment of a permanent bureau for continuing this work so that there shall be somewhere a file of up-to-date information in regard to current health practices and the appropriation, personnel, programs, and procedures of individual departments. This end has been attained by the action of Surgeon-General Cumming in establishing under the United States Public Health Service an office of administrative health practice under Dr. Paul Preble which in close cooperation with the American Public Health Association, is to carry out this important task.

1. Bulletin 136, U. S. Public Health Service.

The second objective of the committee was to provide machinery for giving direct assistance to the health officer who is striving to develop his department to a point of fullest efficiency and for enlisting public opinion behind him in such an effort. This aim too has been attained through the generosity of the Metropolitan Life Insurance Company which has made a grant to the committee for the establishment of a field service. Dr. W. S. Rankin, the able state health officer of North Carolina, has obtained leave of absence to assume the post of field director and will be at the service of members of the American Public Health Association in aiding them through correspondence, personal visits, and special surveys to establish their work on the soundest possible basis.

The American Public Health Association deserves well of the Republic for this constructive effort to better the public service which its members are rendering to their respective constituencies. High professional ambition and a keen sense of public responsibility are thus displayed by this organization of health officials representing the four nations of the American continent. Better official service, wider support of the health program, and substantial reduction in the burden of preventable disease should result from the operation of the machinery thus initiated.

THE past month has been rather solidly filled with health conventions of one sort and another and from each convention the patient objectives of platform oratory—the great mass of the

Convention Oratory

members and hearers—have returned home with mixed feelings. Such and such a speaker gave us the result of important laboratory investigations, another an illuminating analysis of statistical data, a third described some valuable and original administrative procedure. But, Dr. —, how he bored us with an exhaustive history of child hygiene or anti-tuberculosis work and a labored exposition of its well-known principles!

At every meeting we listen to half a dozen of these elaborately written (they are always written) addresses with their strings of platitudes. The presentation of new facts is always worth while. The delivery of a popular address on scientific subjects is worth while, if it be well done and appropriate to the audience; but why a general essay on the elementary principles of some branch of public health to an audience of specialists?

The crux of the whole matter is of course, novelty. The results of research are new. A popular address is new—to a general audience. If a speaker before a technical group has new light on the history of his subject or a new analysis of its general social relationships, well and good. If he has nothing new to say, let him in mercy remain silent.

IF THE public health nursing service, so effectively carried on in the past by voluntary agencies, is to be gradually transferred to the official health agencies of city, county, and state, it is essential that the quality of the service rendered shall remain unimpaired. The nursing service of public agencies is at present less well supervised and

Necessity for Nursing Supervision

on the average less excellent in personnel than that operating under private auspices, according to data presented before the public health nursing section of the American Public Health Association at its Boston meeting. In large measure this is due to the fact that health department nurses are too often scattered through half a dozen bureaus—of child hygiene, of school hygiene, of communicable diseases, of tuberculosis—reporting to the medical or even sometimes the lay directors of these bureaus, with no one to guide and supervise their work who has a first-hand knowledge of its technique.

Where such a condition obtains there is often an astounding waste of valuable training and experience of which the responsible bureau chiefs are quite unconscious because they do not at all realize the possibilities of true public health nursing at its best. The Goldmark report issued last year gave striking illustrations of this condition; and there are city health departments today which boast of the fact that their nurses pay twenty visits a day, with no suspicion that this very fact condemns the service they are rendering. Any sort of a lay worker can drop into a tenement home and say a pleasant word and remind the mother of a clinic date and then pass on again. It is pure waste to use nurses for this kind of service. The function of the public health nurse is really to teach, to demonstrate hygiene in the home. To do this takes time and it takes expert supervision and expert direction. The best standards demand one supervisor to every eight staff nurses; and it is essential for the highest efficiency that all the nurses in a given organization shall be grouped under a single director who is herself a nurse. Under a specialized plan they

may be assigned as regards their daily routine to the directors of other divisions but their qualifications, procedures, and general morale should be maintained by expert professional direction.

THE first annual meeting of the American Child Health Association held in Detroit, October 15-17, was a notable success from several points of view. It brought together from

all parts of the country a considerable number of physicians, health officials, and educators to discuss present day efforts for the promotion of the health of the child.

The Child Health Conference

The program broadly covered all phases of child hygiene from the prenatal period through school life. The formal papers were carefully prepared. A 100 per cent attendance of the speakers and discussants added much to the sessions. A number of round tables for informal discussion provided an opportunity for those with kindred interests to get together and also gave zest to the meeting. The round table luncheon for delegates from the affiliated societies was attended by about two hundred.

An important feature of the meeting was the joint session with the Central States Pediatric Society and the Wayne County Medical Society. Papers of considerable importance were presented on the trend of pediatrics, the growth of our knowledge of infant feeding, the status of mental hygiene of the child and the standards of growth and nutrition. Much interest was shown at several of the sessions in so-called growth and nutrition standards. The consensus of opinion seemed to be that while weight-height-age tables were very useful in interesting the child in its health they should always be used in conjunction with a complete physical examination by a competent physician, when estimating the degree of malnutrition.

Another helpful joint session was held with the child welfare section of the National Organization for Public Health Nursing at which time the problem of early infant deaths was discussed from the standpoint of the physician, the public health nurse and the official agencies.

The public meeting held in St. Paul's Episcopal Cathedral on the opening evening revealed the local interest in child health work. Significant addresses were delivered by Hon. Herbert Hoover, president of the association, and by Dr. George E. Vincent. Both stressed the importance of a careful and painstaking evaluation of child health work, especially in its relation to the broader public health program. Secretary Hoover insisted

that the Association could render its greatest usefulness only in so far as it assisted local communities to face squarely their own child health problems. Definite and concrete methods for individual communities must be based upon a thorough study of local needs. The basic factors in home and community hygiene should never be overlooked.

The sessions and round tables devoted to health education were largely attended and a keen interest taken in their discussions. At one of the sessions a thorough consideration was given to work in health education which should be done by the doctor, the nurse, the teacher, and the nutritionist. At another session the supreme importance of the preschool age was emphasized and practical methods of securing medical examination and supervision detailed.

This conference plainly showed that interest in child health continues to grow and that workers in this field feel the necessity of coming together for discussion of their problems. It brought to a focus various lines of endeavor for the whole child. It brought into strong light the necessity for a national association to so organize as to be able to study local needs and suggest practical methods applicable to the individual communities. As a *sine qua non* for all this the association must have the loyal support of a wide constituency and its work must be guided by sound technical advice.

FOR a number of years Trillat and his associates¹ have been communicating the results of interesting and suggestive experiments bearing upon the relative importance of dust and droplets

Droplet vs. Dust Infection

as carriers of bacterial infection. In a recent communication² Trillat continues his earlier studies by showing that bacteria suspended moist in droplet form penetrate a cotton filter far more readily than when aspirated in a dried powder. Furthermore when guinea pigs inhale droplet infected air the bacteria are drawn into the deepest part of the lungs almost instantaneously while with infected dry dust inhalation for fifteen minutes yields negative results, the bacteria in the dry state being caught by the mucous surfaces, while the droplets, "thanks to their spherical form and surface tension," are not thus fixed.

These experiments appear to be of the first importance in connection with some of the fundamental problems concerned in the etiology of disease. Spherical form and surface tension seem

1. Comptes rendus de l'Académie des Sciences, clvii, p. 873; Vol. 158, p. 1441; clx, p. 153; clxx, pp. 1291 and 1529; clxxiii, p. 109.

2. Comptes rendus de l'Académie des Sciences, clxxvi, p. 144.

however to offer an inadequate explanation of the observed results. It seems possible that the mechanism involved is electrical in nature since it is known that fine water spray particles carry a negative charge while non-metallic dust particles carry a positive charge.¹ In any case the problems here raised deserve the very serious attention of bacteriologists and epidemiologists.

YEAR after year it has proved necessary for leading physiologists and bacteriologists and medical men to journey to their respective state capitols and defend the rights of medical research

Friends of Medical Progress

against the fanatical and unfair attacks of antivivisectionists, and antivaccinationists and others of their ilk. Three times within the last three years—twice in California and once in Colorado—state wide campaigns on a far reaching scale have been necessary to defeat the efforts of the anti-medical cults. Some of the members of these organizations are no doubt sincere but misguided—others are insincere and misleading. As a whole “their status is that of a public nuisance and a serious menace to society.”

If the “antis” should ever gain a temporary victory in any state, not only would the advance of medical science cease but also the manufacture of such primary essentials for the prevention of human and animal suffering as smallpox vaccine, diphtheria antitoxin, and hog cholera serum. It is the general public which would suffer and it is manifestly unfair that the scientific group immediately concerned should continue to bear the whole brunt of defending the cause of intellectual freedom and the service of the suffering against an organized and well financed system of propaganda. We heartily welcome, therefore, the entrance into this field of the Society of Friends of Medical Progress, a national lay society organized and incorporated “(1) To encourage and aid all research and humane experimentation for the advancement of medical science; (2) to inform the public of the truth concerning the value of scientific medicine to humanity and to animals; and (3) to resist the efforts of the ignorant or fanatical persons or societies constantly urging legislation dangerous to the health and well being of the American people.”² The honorary president of the society is President Eliot. Its honorary

vice-presidents include Presidents Angell and Pendleton, Archbishop O’Connell and Bishop Mann, Ernest Thompson Seton and Owen Wister; while its acting president is Professor Thomas Barbour and its field secretary Ernest Harold Baynes. A wide appeal must be made by the motto prefixed to the statement as to why this new society was founded: “If you owe gratitude to any doctor here is a chance to pay your debt”; and the active part taken by men like Mr. Seton and Mr. Baynes should enlist all true lovers of animals in behalf of that scientific progress which since the days of Pasteur has benefited the lower animals quite as much as the human race.

PUBLIC health problems in America are complicated by a factor which is present in no other nation to quite so great a degree, the factor of racial idiosyncrasy. The studies of ten thousand male workers in ten representative industries¹ recently completed by the United States Public Health Service² are of fundamental importance in connection with the influence of such racial factors upon health standards in industry.

Racial Factors in Industry

These studies indicate in the first place that the factors of race distribution and age distribution are almost inextricably intermingled. Thus, in the chief groups under observation, the proportion of workers over forty-five years of age was 3 per cent for the Austrians, Russians, and Poles; 4 per cent for the Italians; 11 per cent for the whites of American birth; 21 per cent for the colored; 23 per cent for the Irish; 25 per cent for the German; and 27 per cent for the English. Height ranged from an average of 65.5 inches for the Italians to 67.9 inches for the American whites, the order being Italians, Poles, Russo-Austrians, English, German, Irish, colored, and native white. The Poles, Russians, Austrians, and Italians were markedly heavier for a given height and age than the German, Irish, American, and English. Even the pulse rate showed marked racial differences, the Poles showing the lowest figure (80.3) followed by the Russo-Austrians, colored, English, Italians, Irish, American whites and Germans (83.3), the extreme differences though slight being well in excess of the probable errors.

Three Years of Student Health at University of Kentucky

What a Small University With a Limited Equipment Has Been Able to Do for Its Students

THE University of Kentucky has had, during the past three years, a department of student health. The personnel of this department consists of two physicians, a graduate nurse and a secretary, all on full time, serving under Dr. P. K. Holmes, director of the Department of Hygiene. A dispensary is maintained upon the University campus. It is open from 8:30 a. m. to 5:30 p. m. for the benefit of students and faculty. It was nearly a year before all the students in the various colleges knew of its whereabouts, and the extent of its service, but an increasingly larger number of students are availing themselves of its service each year.

As the function of the department is primarily prevention, serious and long protracted cases of illness have been cared for by local rather than by department physicians. As far as possible the work of the department has been confined to the campus and limited to regular office hours. It is very much worth while to educate students into coming to the dispensary for treatment for beginning colds, inflamed tonsils, slight wounds, headaches and such minor infirmities rather than through neglect of such conditions to over-look the early stages of serious, communicable illnesses. Students are also encouraged to come at any time to the department for advice as to how to avoid illness by healthful living. Such preventive treatment has served very effectually in checking serious illness.

During the first year of the department the men students made 1,533 calls and the women 835 calls at the dispensary, with a total of 2,368. The campus enrollment was 1,259. The number of faculty cases attended to at the dispensary and at home were women, 77; men, 21. There were two deaths during the college year, one from illness and one from drowning.

The total number of cases cared for by the resident nurse in the girl's dormitories was 844. Only six cases of the more common communicable diseases (mumps and chickenpox) were recorded during the year. A case of smallpox was detected in its early stages and all the students with whom the patient had come in contact on the day of the appearance of the characteristic symptoms, which numbered 182, were immediately vaccinated, with the result that no further cases developed. One hundred

third years the upper class women had to be omitted because of pressure of time. During the second and third years, in order to get through with the physical examinations more quickly four local physicians were added to the staff for part time. Students showing need of further attention have been summoned to the dispensary at the necessary intervals. Local physicians have cooperated with the department to the extent that students sent to them with a letter from the department were charged in proportion to their ability to pay; in many cases no charges at all have been made. A report of the examination is sent to the students' parents, one is given to the student himself, and another is kept on file in the office of the department.

The number of girls excused from gymnasium exercises as a result of excuses written by family physicians has been cut down by approximately 75 per cent. It has been the custom of many girls who have been disinclined toward physical exertion to ask their family physician for an

excuse, and in many cases such excuses have been written for no other reason than to please a patron. The Physical Educational Department, greatly handicapped by such measures, has heretofore been powerless to reject such excuses. With the department of health upon the grounds, no exemption from gymnasium work for physical disability is granted except through the University Health Department.

A Dental Clinic is conducted each year by a local dentist, under the direction of the department's resident nurse. Every student in the University is required to have his teeth examined and a record made of the findings. A card containing this record is given to the student, one is sent to the parents of the student, and one

The personnel of the Department of Hygiene, University of Kentucky. From left to right: Dr. Herring, Dr. Hunt, Miss Moffett, Dr. Holmes, Dr. McLean, Dr. Elliott, Miss Desha, Dr. Lipscombe.

thirteen vaccinations for typhoid prevention were given; twenty-five x-ray examinations for diagnostic purposes were made, and 131 individuals students were sent for treatment to local physicians with letters of introduction from the department.

During the second year of the department the men students made 2,851 calls and the women 689 calls at the dispensary, with a total of 3,540. The campus enrollment was: Men, 1,015; women, 464; or a total of 1,479. The number of faculty cases was 57 men. The total number of cases cared for by the nurse in the girl's dormitories was 1,659.

Every student in the University was given a physical examination by the department physicians during the first year. During the second and

is kept on file in the office. Those needing attention are followed up and urged to remedy the defects shown. As a result of the dental clinics, cavities have been reduced 35 per cent, diseased conditions of gums 66.6 per cent and general uncleanliness of teeth 16 per cent.

During the past year over 735 students have been enrolled in the various hygiene classes.

Eight hundred seven individual student conferences in reference to health (other than dispensary calls) were held with the members of the staff.

A weekly health article has been published by the department in the Sunday papers of the larger cities of the State for the past three years.

Last year twenty-nine addresses upon general health subjects were delivered in and out of the state.

A correspondence course in General Hygiene is offered to the teachers and others of the state. Four extension courses in General Hygiene, two hours a week throughout the year, have been conducted at different cities.

The first year's work of the Department of Hygiene and Public Health warranted its further existence. In establishing such a department the University has recognized instruction in health as a part of the regular program of education. It has for the first time in its history become responsible for more than imparting the regular class room instruction.

Nothing in the nature of an epidemic has occurred on the campus during the past three years. The number of acute contagious diseases has been very small. The absence of any considerable amount of serious illness upon the campus has been conspicuous. This has been due partly to the mild open winters of the past three years, but also very considerably to the work of the department. During the college year preceding the advent of the Health Department 7.7 per cent of all recitations were missed by students because of illness as against 4.1 per cent for the following. Last year it was 5.1 per cent. Twenty-four cases of acute infectious diseases were reported the preceding year as compared to six cases the first year of the department. It would be only fair to assume that quite a few cases the preceding year were unrecorded, owing to the absence of facilities for recording them. This would make the comparison even greater.

From the standpoint of imparting health knowledge for present and fu-

ture living, cutting down class room absences, preventing the spread of communicable diseases, lowering the cost of operating the University, lessening the burden of responsibility on the part of the officers of the University for the health of the students, diminishing physical morbidity and probably saving life, the department has been invaluable.

Educators are just waking up to the fact that our educational institutions must assume responsibility for

Dr. E. C. Elliott, chief of the Dental Clinic, University of Kentucky.

the health, social welfare, and physical education as well as for the mental education of the boys and girls who come to their doors. Therefore, the maintenance of an adequate department of Hygiene and Public Health is an absolute necessity.

This is not a record of anything at all unusual in university health organization but just a statement of what a small state university with very limited equipment is doing for its students when here-to-fore nothing at all of any importance had been done.

Examinations for Motor Drivers

No tests, medical or other, according to a current writer in the *Lancet*, can guarantee a fool-proof state of affairs, but much improvement in the accident potential of motor drivers in general can be effected through searching and stringent efficiency tests as a basis for the granting of licenses. Questions are often raised which even suggest the advisability of compulsory health certificates for motor drivers. "What, for instance," says the comment, "is the physician to

do who is consulted by an epileptic chauffeur?" If the chauffeur insists on continuing his employment, the physician is faced with the disagreeable alternatives of warning the chauffeur's employer or being held responsible for some fatal accident at a later date.

Le Scalpel recently made the recommendation to the Academy of Medicine in Paris that no motor driving license be given to anyone under the age of twenty-one; that chauffeurs suffering from faulty vision or hearing should be subjected to medical examination by a specialist every year; and that no license should be given to anyone without a medical examination in which the heart, the arterial pressure, and the functions of equilibrium and coordination have been found to be in good order.

The first of these considerations, it would seem, over-shoots the mark, for the simple reason that reckless fools remain reckless all their lives; the age of twenty-one is no deadline. Level headed persons are level headed in their teens. The other two considerations deserve serious attention. A recent serious accident was attributable to total deafness on the part of a driver. It might be well if such diseases as epilepsy, chronic alcoholism, and addiction to drugs were made disqualifications for driving licenses. A satisfactory medical examination is not, of course, a guarantee of physical and mental fitness; and it is obvious that a given driver may be physically and mentally fit to amble along at ten or fifteen miles an hour through a deserted lane who would break down in congested traffic.

The mounting death rate from automobile fatalities in the United States, apparently exceeding in 1923 the country-wide rate of 12.9 in 1922, demands attention to all the factors involved. Analysis of causes in the 1,501 automobile accidents in Massachusetts in 1921 places the responsibility on the driver in nearly 81 per cent of cases.

The Low Toxicity of Saccharin

A curious accident reported from Germany (*Münchener medizinische Wochenschrift*, Vol. 69, 1923, p. 968) suggests how slight is the danger from the quantities of this substance which might ordinarily be ingested in artificially sweetened foods. A boy of 9 years swallowed 200 saccharin tablets totalling 3.5 grams. He suffered from a brief loss of consciousness, hallucination, motor disturbances and acute urticaria but experienced a rapid recovery.

Practical Hygiene and Sanitation Dennison Manufacturing Co.

By HALSTEAD G. MURRAY, M.D., FRAMINGHAM, MASS.

THE following is an attempt to describe briefly some of the features of the medical, dental and sanitation work of the Dennison Manufacturing Company, Framingham, Mass. The total number of employees is at present about 3,200, of whom approximately half are women. The work done by women is, for the most part, of a light nature, practically all being done sitting. The work done by the men is of varied types ranging from very light work to extremely heavy work such as the trucking of heavy rolls of paper.

The main objective sought by the company through its health departments is the prevention of disease and accidents, thus helping to establish a healthier, happier, and more efficient working force.

Medical Department

Giving their whole time to the health work at the Dennison factory there is a physician, a dentist, and two graduate nurses as well as a stenographer. The clinic, or the dispensary, is centrally located and easily accessible to all employees. There are six rooms of good size, including a waiting room, a large room where accidents and minor ailments are cared for, a physician's private office for physical examinations and consultations, a dental clinic, a small rest room for the men and a large room attractively furnished with wicker chairs, couches and screens, for the women's rest room. There is also one other room, the nurses' room, and here women are given their physical examinations. It is furnished in the same style as the women's rest room and does not give one the feeling of being in a hospital. The women's rest room occupies approximately 924 square feet, while the rest of the clinic occupies about 1,728 square feet.

These rooms are fully equipped for any emergency that may develop during the course of the work and the

average daily attendance for surgical or medical care is 75 persons. The most frequent complaints are caused by headaches, colds, sore throats, conjunctivitis, boils, acne, dysmenorrhea, constipation and indigestion. During the course of the year many other minor ailments are cared for, but the above ailments are by far the most frequent. Those persons coming to the clinic for more serious ailments are examined and usually referred to their own physicians for further care and treatment.

An idea of the amount of work done

chief clerks, and department heads, totalling about 100, are given a physical examination about twice a year. For this latter group there is a questionnaire on personal hygiene, personal and family history, and a complete physical examination which includes urinalysis. Any employee who desires it may have a physical examination on request. The company maintains a fire department of its own, and these men also are examined annually.

The physical examinations given new employees are an effort to help the employment department place

men and women more efficiently with respect to the work to be done, as well as to advise these persons of their minor defects and what measures of correction should be taken. It also gives the examiner an opportunity to stress certain points on personal hygiene.

The basis for rejection is to exclude only those who would be considered a danger to their fellow employees or a danger to themselves if placed on certain types of work for which they are physically unfitted. In 1922 only 18 were rejected for the job for which they had chosen out of about 700 examined at time of employment.

During the same year seven of this number had their defects remedied and were given work at the plant. This is a very small percentage of rejections, but the work is so varied in this particular industry that it is comparatively easy to place persons who are not suffering from some very serious defect or disease.

The examination of persons transferred to different work in the plant is most important, as it is easily possible to place a man on work which might readily aggravate existing defects in his physical makeup.

Persons under 17 years of age are watched closely by two physical examinations a year, and more often if necessary. This is done chiefly be-

The Dental Clinic. This is a part of the medical clinic and comes under the supervision of the clinic physician.

by the clinic may be gleaned from the figures for the month of May, 1923.

During that month 1,874 treatments were given, 178 accidents were reported, and 264 physical examinations were given.

The following list shows the number of different common ailments treated during the month of May:

Coryza, sore throat and other upper respiratory affections	131
Digestive troubles	59
Headache	50
Dysmenorrhea	59
Conjunctivitis	22
Boils	6

All new employees are given a physical examination before being put to work, as are also all employees transferred to a different type of work. All persons under 17 years of age are given a physical examination twice a year. A group of foremen,

cause these young people do not have the usual medical care and observation afforded by most public schools and to make certain that the work they are doing is not interfering with their normal development. We have been able to get these young persons to have many of their minor defects corrected, such as defective vision, poor teeth, bad tonsils and adenoids, and in some cases they have had hernias corrected by operations with much benefit to themselves.

There are several known cases of arrested tuberculosis in the plant. These are followed up every four months at the present time. With our lung cases we are fortunate in having the consultation services of the Community Health Demonstration, an experiment being carried on in Framingham under the direction of the National Association for the Prevention of Tuberculosis. This has been of great value to us.

Education

An article on Health and Disease appears in each issue of "The Round Robin," which is published once a month and given to every employee. The bulletin boards are used at various seasons of the year in an effort to instruct the people how such common infections as grippe, colds, sore throat, etc., may be guarded against. Talks have been given to the members of the Mutual Relief Associations and at foremen's meetings on such subjects as physical examinations and accident prevention. The factory library and the circulating bookcase, which moves from one department to another until the plant is covered, contain books on health which have been written for the lay public. These books are called for as much as any one type of book.

Two Other Features

Not the least of the medical services offered is what is called the "Nutrition Class" and the "Posture Training."

The Nutrition Class is made up of girls who are "run down" below par, convalescing, or more than ten pounds under weight. This group is given ten minutes mid morning and afternoon rest periods and are supplied with a ten-ounce glass of malted milk or plain milk. This work is under

the supervision of the nurses. Each girl has a physical examination before joining the class, with a talk by one of the nurses regarding her living habits and diet. These girls have averaged a gain of three pounds per month and have showed other signs of improvements in health.

In the Training Division or school, of the factory, where most of the women workers are taught the work before going out into the producing departments, we have one of the nurses spend a few hours each week instructing the new workers just how to use the adjustable factory chairs and how to sit at their work properly. The work is being extended to the producing departments for the older

common injuries which we have.

Among those injured in the factory during 1922 we had no infections resulting in any time lost from work among any of those who reported for treatment on the day of the injury. This shows the value of early treatment of all injuries no matter how trivial. Of those not reporting to clinic on day of injury we had 79 infections. Six of these had a total lost time of 76 days.

All injured persons who are able to be about or who do not live in outside towns are treated at the factory if able to work, whether they were injured outside or inside the factory. The routine treatment of minor injuries has been cleansing the wound with applications of 3 per cent tincture of iodine, sterile vaseline and gauze dressing.

Dental Clinic

The number of persons found with defective teeth, was so great and systemic effects of bad teeth are often so serious that the company decided to install a dental clinic with a full time dentist in charge. A complete dental unit was installed and the work is done on a cost basis except for emergency work, which is free of charge. The dental clinic has been in use for about one year and the dentist has been kept busy

The Medical Clinic. In this room accidents and ailments are treated. On the left is the coryza closet and on the right the doctor's private office.

employees. Posture plays a large part in fatigue and is a very important part of health supervision in industry.

There is a Safety Inspector who supervises and plans the safety work. Many safety devices are suggested through the Factory Suggestion System, and through the Committee on Health and Safety, composed of two members of the management and two members of the Factory Works Committee. There is also a Safety Committee composed of the Safety inspector, plant physician, and four workers from the factory whose term of office is four months, when four new men are asked to serve. These four workers cover the entire plant once a week on a safety inspection and report findings to the Safety Inspector. Education in regard to safety is carried on continuously. Each new employee is instructed regarding any dangerous parts of his machine or job and given a booklet on safety which tells how to avoid the most

every day.

The work is limited to extractions, fillings and prophylactic work. The employees make appointments through their foremen or Works Committee Representative. The appointments are usually for a period of thirty minutes or longer if the dentist desires it. Employees lose time while in the dental clinic and pay for cost of material used and 75¢ per half hour for the dentist's services. The dentist is paid a straight salary by the company. The following will give an idea of the work done during the first six months after the dental clinic was installed.

Total number of visits.....	1,163
Total number of extractions.....	156
Total number of cleanings.....	239
Total pyorrhea treatments.....	15
Total emergency treatments and other treatments.....	607
Total devitalization.....	18
Total amalgam fillings.....	359
Total root fillings.....	47
Total synthetic fillings.....	180

Total cement fillings.....	32
Total gold inlays.....	9

Lighting and Eye Conservation

All new employees are given tests for distant and near vision, if errors of refraction are found, they are told what the results may be if these errors are not corrected and retinoscopic examination is made at this time. Corrective lenses are placed in the trial frame to show the improvement in vision by having proper glasses. This helps considerably to influence the new employees to obtain suitable glasses. On certain types of work persons with defective vision are required to have suitable glasses within two weeks after employment.

The natural lighting of all rooms is good and the artificial lighting is of the latest type with a general average of four-foot candle meters throughout the plant, and on special work the number of foot candles run as high as sixteen. The arrangement of the lighting system keeps glare and shadows to a minimum.

Sanitation

The sanitary arrangements are carried into effect by the engineering de-

partment in cooperation with the plant physician.

The toilet and washing facilities of course comply with the state laws relating to these subjects, and in most departments the facilities are far beyond any legal requirements. Individual paper towels are furnished to each employee, also liquid soap. Dressing rooms and shower baths are provided for those whose work is of such a nature that a daily shower bath is necessary from a standpoint of health and cleanliness. Such a place is the foundry where the electrotype work is done. Dusty processes where fumes might be a hazard are carefully protected. Sanitary drinking fountains are well distributed throughout the plant, the water being cooled with ice from May 1 to October 1 each year. Damp sawdust is used by all sweepers to keep dust to a minimum and much of the sweeping is done after working hours.

All of the features of the medical, dental and sanitation work have been put into effect not from any paternalistic spirit but because the management after thorough consideration fully believes that such work pays large dividends, keeping the employees contented and efficient.

Relation of Laboratory Aids to Practice of Medicine

THE development of laboratory aids to diagnosis is reviewed by Lewis A. Conner, (*Journal A. M. A., Sept. 15, 1923*). The rapid increase in the number and in the complexity of the laboratory aids has been associated with a profound change in the character of the instruction given to our medical students. The work required in physiology, in biologic chemistry, in bacteriology and in immunology has increased by leaps and bounds because of the ever growing application of these sciences to the clinical branches; and the additional time needed for these basic sciences has, to some extent at least, been taken for that formerly allotted to the more strictly clinical study of patients. The increasing emphasis laid on these rapidly developing laboratory methods has changed in some degree the attitude of the student toward clinical medicine. The so-called "exact" methods of investigation seem much more important and much more satisfactory than the less tangible and less "exact" study of the patient him-

self and of the history of his illness. The making of a Widal test appears so much simpler and more convincing a method of establishing the diagnosis of typhoid than a painstaking analysis of the patient's history and a thorough physical exploration; the reading of a roentgenogram of the chest seems such a refreshingly short cut to the diagnosis of pulmonary tuberculosis; the electrocardiogram demonstrates so readily, and with such a saving of intellectual effort, the existence of, say, a two to one heart block, that it is not to be wondered at that most medical students and interns should now leave the hospital wards and go out as practitioners imbued with the feeling that all these laboratory and instrumental aids are a necessary and indispensable part of their professional equipment. They have come to lean on these more heavily than on the more strictly clinical methods of examination. This attitude on the part of the well trained young practitioner has been perhaps the most important single

factor in deciding to shun the rural districts and smaller towns in choosing the location for his practice. However, it is only by the help of these laboratory aids that modern clinical medicine and surgery have made, and will continue to make, their chief advances. But the indiscriminate application of many of the more complicated and delicate of these procedures to the individual problems of the practitioner is not necessary and will often serve to confuse rather than to clarify the issue. The special field for such tests lies in their application to the problems of clinical research, as these are carried on in thoroughly equipped hospitals, manned by highly trained and carefully chosen workers. Under such circumstances these tests are invaluable in bringing to light new clinical features or in making more understandable those already known. Connor pleads (1) for greater attention on the part of teachers to the need of establishing in the minds of students a truer perspective of the proper relationship between laboratory aids and the older bedside methods of clinical study, and an appreciation of the importance of acquiring skill in the latter methods; (2) for a sense of greater responsibility on the part of the general practitioner for the trustworthiness and accuracy of the tests employed by him and for a proper understanding of the principles; the significance and the limitations of application of such tests, and (3) for an effort on the part of all of us to resist and counteract the growing inclination to regard the use of laboratory and instrumental aids as the chief means of diagnosis and to give too little weight to the more laborious but more important measures of painstaking clinical observation and careful deductive reasoning.

Insurance Contributes to Public Health

Two hundred ninety-two life insurance companies in the United States disbursed in 1921 a sum approximating ten million dollars to physicians for medical examination of life insurance applicants. The scientific value to medicine of opportunity to examine large numbers of presumably physically unimpaired persons is very great, and even greater from the public health viewpoint is the value of the service of many life insurance companies of extending free of cost to policy holders, the privilege of periodic health examination.

Annual Meeting of the American Public Health Association

THE Fifty-second Annual Meeting of the American Public Health Association was held in Boston, October 8 to 11, under the presidency of Dr. E. C. Levy of Richmond, Va., with more than seven hundred persons in attendance. Detroit was selected as the meeting place for 1924. Officers for the ensuing year were elected as follows:

President, W. H. Park, M. D., director, Bureau of Laboratories, New York City Health Department.

First vice-president, Francis X. Mahoney, M. D., commissioner, Boston City Health Department.

Second vice-president, J. W. S. McCullough, M. D., commissioner, chief officer of health, Province of Ontario.

Third vice-president, W. H. Davis, M. D., chief, Division of Vital Statistics, Bureau of the Census, Washington, D. C.

Treasurer, R. I. Lee, M. D., professor of hygiene, Harvard University.

Secretary, James A. Hayne, M. D., commissioner of health, South Carolina.

Members of executive board, H. F. Vaughan, Detroit, Mich., M. P. Ravenel, Columbia, Mo., and E. C. Levy, Richmond, Va.

Section Officers, 1923-1924.

Laboratory—Chairman, A. P. Hitchens, M. D.; vice-chairman, Benjamin White, Ph. D.; secretary, J. F. Norton, Ph. D.

Public Health Administration—Chairman, C. C. Slemons, M. D.; vice-chairman, C. V. Craster, M. D.; secretary, Stanley H. Osborn, M. D.

Vital Statistics—Chairman, W. J. V. Deacon, M. D.; vice-chairman, Stewart Thompson; secretary, John O. Spain.

Sanitary Engineering—Chairman, H. A. Whittaker; vice-chairman, Langdon Pearce; secretary, George W. Simons, Jr.

Industrial Hygiene—Chairman, C. E. Ford, M. D.; vice-chairman, H. F. Smyth, M. D.; secretary, E. R. Hayhurst, M. D.

Food and Drugs—Chairman, W. D. Bigelow, Ph. D.; vice-chairman, H. W. Redfield; secretary, James O. Jordan.

Child Hygiene—Chairman, Taliaferro Clark, M. D.; vice-chairman, Charles H. Keene, M. D.; secretary, C. E. Turner.

Health Education and Publicity—Chairman, H. E. Kleinschmidt, M. D.; vice-chairman, B. R. Rickards; secretary, Marjorie Delevan, R. N.

Public Health Nursing—Chairman, Margaret K. Stack, R. N.; vice-chairman, Mary Laird, R. N.; secretary, Agnes Martin, R. N.

Among the resolutions adopted

which dealt with matters of broad general policy were the following:

Whereas, The periodic physical examination of apparently healthy individuals is the keystone of personal hygiene and one of the most valuable methods of fostering general public health;

Therefore be it resolved, That the American Public Health Association urges all citizens of the countries represented by its membership to have such annual medical examinations made;

William Hallock Park, M.D., L.L.D., the newly elected president of the American Public Health Association is professor of bacteriology and hygiene, University and Bellevue Hospital Medical College. He has been director of the New York Health Department Bureau of Laboratories since 1884. Through his pioneer work in the up-building of the New York City laboratories Dr. Park has exercised greater influence than any other living man upon the development of the public health laboratory in America, and his contributions to science have made him one of the leading authorities of the world in regard to the bacteriology and serology of diphtheria.

And be it further resolved, That the American Public Health Association indorses the campaign for Health Examinations now being conducted by the National Council.

Resolved, That the American Public Health Association confirms its belief in the value of, and the need for, a program of health examination and health supervision of all school children, which program should include health education and training in both health habits and physical activities.

That the A. P. H. A. favors the placing of the regular sanitary engineers of the U. S. P. H. S. on the same commissioned status as the regular medical officers in that service and

therefore authorize the appointment of a committee to act for the association on this matter and not to cooperate with similar committees of the Federated American Engineering Societies and of the A. S. C. E.

At the first general meeting of the association the delegates were welcomed by the Hon. James Jackson, treasurer of the Commonwealth of Massachusetts, representing the State, by his Honor, Mayor James M. Curley, and Dr. F. X. Mahoney, health officer of Boston, representing the city, and Dr. D. L. Edsall, representing the Harvard School of Public Health. Addresses of response were made by Dr. C. V. Chapin on behalf of the delegates from the United States and by Dr. Peter H. Bryce, on behalf of the Canadian delegates. Cuban and Mexican representatives, so prominent in the past, were unfortunately absent this year. Dr. Levy's presidential address dealt with the reciprocal relation between the health officer and the physician and emphasized the importance of a mutual comprehension and a close cooperation between these two groups.

The association entertained a distinguished guest in the person of Sir Thomas Oliver, pioneer in British industrial hygiene, and at the second general session Sir Thomas recounted his early investigations on lead poisoning at Newcastle and in Hungary and on "phossy jaw" in London, which have proved so basic in the modern control of industrial poisonings. He commented on the progress made in the United States in this field since his last visit to the country in 1912 and particularly on the growth of industrial medical service in which America has surpassed Great Britain and emphasized fatigue as a problem of industrial hygiene and the importance of abolishing the twelve-hour shift, and relieving monotony of work by every possible means. Dr. L. R. Williams of the National Tuberculosis Association spoke on coordination of national health work, defining

the objective of the voluntary health agency as the stimulation of official leadership and the mobilization of proper cooperation. He recounted the remarkable achievements of the National Health Council in coordinating the work of the various voluntary national health agencies and urged further progress along this line. Dr. G. E. Vincent, president of the Rockefeller Foundation, in speaking on "Weighing the Ounce of Prevention," made one of his inimitable addresses which kept the audience in uproarious delight and yet lodged with complete effectiveness the serious message that we must strive to let the public comprehend the real significance and limitations of medical science, and must furthermore formulate clearly the relative values of various types of public health activity.

The public health administration section opened with an address by the chairman, J. W. S. McCullough, on "The Full Time Health Officer." In the course of the discussion it was pointed out that the full time health officer is only the first step toward effective service, since he can accomplish little without staff and appropriations. The full time health department *must be our ideal*. C. E. Turner presented the report of the committee on standardization of public health training, reviewing the advanced degrees in public health granted during the past year and also presenting a special study of the courses in public health offered to medical undergraduates in the leading schools of the United States.

At the second meeting of the section C.-E. A. Winslow presented the report of the committee on municipal health department practice (see editorial discussion, p. ...) and M. P. Horwood described his recent tuberculosis survey of Philadelphia. This survey has already led to marked progress in the creation of a new division of tuberculosis under the municipal health department, the assumption by this division of the direction of the clinics hitherto maintained by the state and the development of an industrial program under the guidance of the local Health Council.

At the third session a most enlightening symposium on the health department of the small community was presented under the leadership of G. C. Ruhland. I. V. Hiscock presented a study of the organization of twenty-one health departments in Connecticut cities of about twenty thousand population, showing a total per capita expenditure by official and unofficial

health agencies of \$0.52 (\$0.19 by official agencies). A special study of five selected cities in different sections of the country having particularly good organization showed a total expenditure of \$1.22 per capita (\$0.85 by official agencies); and an ideal program suggested by Professor Hiscock calls for an expenditure of \$1.90 per capita. W. H. Brom emphasized the importance of surveying the work of all official and unofficial agencies bearing on child hygiene and the formulation of a constructive program for the future. I. D. Rawlings described the practice in Illinois of permitting modified quarantine to be used in small communities when, and only when, these communities have the machinery to make modified quarantine effective. M. N. Baker emphasized the importance of securing engineering advice in regard to refuse disposal and urged the value of simple methods such as burial and particularly the feeding of garbage to hogs. Donald B. Armstrong presented the National Health Council campaign for health examinations and W. G. Exton the work of the Prudential Life Insurance Company along this line.

At the final session of the section Eugene R. Kelley, in a paper on the public health administrator's relation to the cancer problem, said that there is a glaring lack of decent facilities for the care of cancer patients, the district nursing association being often the only agency which attempts to mitigate the sufferings of these unfortunates. The provision of means of early diagnosis is clearly the health administrator's job, but even with this provided there yet remains the task of educating the physician to its use. Popular information regarding cancer is not yet out of its swaddling clothes; the great majority of small private or semi-private hospitals are not alive to their responsibility, and few have any pathological service. L. I. Dublin asked that cancer be made a reportable disease and Dr. Chapin suggested that during "cancer week" this year the inauguration of such activity by every health department as its contribution would be of immeasurable value.

Francis McCloskey read a paper on the application of the practice of office business and routine to health departments. The value of interdepartmental conferences at regular intervals was emphasized as well as the folly of delegating authority to department heads and then attempting detailed control by the chief administrator. It is important to remember that the public's reaction to a health

department is largely determined by contact with its subordinate employees.

"Nuisance Prevention, a Hindrance to the Prevention of Disease," was the title of a paper by Charles V. Chapin. Pointing out the many untouched fields of health work that are crying for attention, Dr. Chapin declared that nuisance prevention does not pay. In the eighty-three cities surveyed by the committee on municipal health department practice about \$2,800,000 was spent for sanitary inspection. The public still believes that all dirt is dangerous and that odors are deadly, but a dead cat on the street does not cause diphtheria and an uncovered cesspool is a cause of death only by drowning. In Providence, with a population of 250,000, only half the time of one inspector is now devoted to nuisances, and nuisances of no health menace are nominally cared for by the police.

A lively discussion followed, in which it was generally agreed that the city health department wasted a great portion of its appropriation in abating nuisances to the eye and nose, which have no bearing on the community health. In rural regions, particularly in the hookworm zone, the insanitary privy is a nuisance of great importance. It was also suggested that as long as the public continued to look at the abatement of nuisances as the chief function of the health department it would be necessary to devote time and money to the continuance of this activity in order to secure popular support.

W. F. Snow presented the report of the committee on venereal disease, which showed that court decisions have tended to uphold the health officer in dealing with the venereal infections as with any other kind of communicable disease. All persons known to have been exposed or reasonably suspected of infection should be examined, and those convicted of sex offenses can reasonably be suspected.

Isaac D. Rawlings presented a paper and also read one for Herman N. Bundeson dealing with the rules and regulations and standards of infectivity and laboratory methods in force in Illinois and the city of Chicago which have made possible the accomplishment of a large amount of work. Dr. Dixon expressed his opinion that police methods are not good in the control of the venereal diseases, stating that in Detroit while ninety cases per month were brought in by the police, ten thousand came voluntarily to clinics.

The laboratory section held three

sessions with papers of particularly high quality. Among those of special importance at the first session may be mentioned a discussion of administrative problems of the public health laboratory by L. C. Havens which contained many good practical hints, a report by Max Levine and C. S. Linton on progress in the differentiation of *Baerogenes* strains from soil and feces, and a fascinating address by R. P. Strong in which he described a flagellate parasite—a *Euphorbia*—which he believes that he has also isolated from a hemipterous insect feeding on the *Euphorbia* and from a species of lizard found in the vicinity. In one case he even believed that the injection of the flagellate from the lizard produced a local infection in the monkey.

At a second session E. O. Jordan reported on behalf of the committee on standard methods, the only final and definitive action recommended, being the acceptance of the U. S. Public Health Service method of testing disinfectants in place of that formerly set forth by the A. P. H. A. Leonard Greenburg described the impinger, a new device for sampling atmospheric dust which is far more effective than the Palmer apparatus, giving 96 to 98 per cent of the total dust present (as shown by optical methods) in the case of silica and 66 per cent of the smoke particles in the case of tobacco smoke.

At a third session C. C. Young and R. L. Kahn reported favorably on the use of the Kahn precipitation method on the basis of 58,000 tests and P. K. Olitsky and J. E. McCartney described an important series of experiments on the etiology of the common cold. They believe that two distinct types of cold exist, one communicable and the other non-communicable, and have succeeded in transmitting the former type in a clear filtrate from the mucous secretions of early cases. Neither *B. pneumoniae* nor the globoid bodies of Foster are indicated as the causative agents.

A striking report was presented by F. W. Sears on the progress of diphtheria immunization at Auburn. In the year before his campaign began 22,438 school days were lost as a result of diphtheria, equivalent to a waste of \$10,860 worth of educational facilities. After the campaign the time lost on account of diphtheria involved a money loss of only \$500. W. H. Park and E. J. Banzhof made a final report on the relation between toxicity and immunizing value of T A mixtures. M. C. Schroeder discussed the duration of immunity, with and

without the repeated stimulation of the Schick test, and Benjamin White described the reactions obtained among different groups of the Massachusetts population. The net results of this discussion, which proved to be one of the most important of the convention, were to demonstrate that immunity against diphtheria varies with density of population and consequent opportunities for exposure (Boston schools 50 per cent immune, remote towns and certain private schools none immune); that it is affected by race stock, Italians showing relatively low immunity; that immunity, whether due to infection or artificial immunization, lasts at least five years; that Dr. Park's .1 L + treatment is highly efficient and free from objectionable reactions; that English studies on immunization by the use of toxoids deserve careful consideration; that immunization by private physicians before children enter school should be urged as strongly as possible but that Schick-testing should generally be done by public officials experienced in this particular technique.

Vital Statistics

The opening address before the vital statistics section was a preliminary report by Frederick L. Hoffman of an investigation of health in the printing trades, directed by Dr. Hoffman and sponsored by the Joint Council of Employers and Employees with the cooperation of the Bureau of Labor. It represents the largest voluntary investigation heretofore undertaken within a single industry. The mass of data is so great that another year will be required for its complete analysis by occupations within the industry.

Partial analysis now completed is convincing of wide prevalence of extensive impairment of eyesight. It is not easy to differentiate what health influences are significant, on the chemical side particularly, but it is clear that compared with thirty years ago working conditions have improved enormously as regards dust and fume removal; that predisposition to tuberculosis said to exist in England does not prevail here; and that health conditions are on the whole good. William H. Davis, in a paper on public health in Boston, brought out carefully weighed evidence that health effort in Boston looking toward maternal welfare must be specifically directed toward the care of mothers born in Ireland, owing to the relatively high mortality of mothers of this race. The significance of the facts was further emphasized by Louis I. Dublin's

studies contrasting maternal mortality figures in Ireland with those of the Irish born who have come to the United States.

An important move toward simplification of statistical record through the evolution of a standard shipping permit for the transportation of dead bodies was made when the preliminary investigations undertaken by an Illinois group, headed by Sheldon Leavitt Howard, were referred to a committee to report to the Vital Statistics section in 1924. It was made evident that needless hardships and excessive costs are imposed by sanitary requirements based upon archaic notions of communicable disease hazard involved.

By far the most significant discussion before the section had to do with the importance of contributory causes of death, for the primary cause—nephritis, cerebral hemorrhage, or heart failure—may be a manner of dying and not a guide for disease prevention. Even an associated disease—such as measles connected with the accidents of pregnancy—may be of far greater moment to the epidemiologist than the primary cause of death. Louis I. Dublin handled this subject and pointed out the discrepancies in existing practice. It is especially significant that alienists derive slight benefit from statistics because mental disorder is successfully concealed by current records. The requirements of preventive medicine will be better served when the committee delegated to this task can work out titles and sub-titles that admit of better interpretation in rheumatic endocarditis, malarial hepatitis, diabetic gangrene, syphilitic rheumatism, and other such conditions.

John O. Spain further illuminated this subject by showing the difficulties of assignment through the increasing percentage of joint causes of death. The joint cause, such, for instance, as influenza in pregnancy, may account for as much in either direction as one-third of the normal rate. The whole matter was referred to a committee of seven for elucidation.

Charles V. Craster presented figures showing a curious distribution of heart disease by states, not explainable on the basis of causes usually assigned. Recent interest in this subject has developed the facts that many more hospital beds are needed for these patients than any community has provided; that clinical study of such cases is lacking because heart patients are everywhere sacrificed to more urgent conditions; and that curative measures are almost at a standstill. Rheu-

matism was assigned as the chief causative factor.

Gaius E. Harmon developed a study of the course of mortality from puerperal septicemia during 1920-21 showing that (1) the moving average reveals a five-year cycle; and (2) all states show a significant decline since 1909.

Before a joint session of the Public Health Administration Section with the section on Vital Statistics, James A. Tobey discussed the coordination of public health laws in the United States. The need seems to be for better rather than more laws. A model state health code is needed and should be worked out. The organization of a bureau to collect present state laws and to present them in an accessible and comparable form would be of great value as a preliminary study to the formulation of a model code.

A paper on the elements of a complete morbidity and mortality report was read by Haven Emerson in which it was urged that the present flood of reports abandon the crude and adopt standardized rates; that reductions in mortality be always presented by age groups; and that data be presented in more detail as to sex, race, etc.

At a final section devoted to epidemiology, the most important papers were presented by Norman Lothian, field epidemiologist of the Health Section of the League of Nations, who described a noteworthy service now rendered by the section through its publication of epidemiological intelligence; and by Millard Knowlton and I. V. Hiscock, who reported on the recent outbreak of amebic dysentery at Ansonia, Conn.

Sanitary Engineering

Following opening remarks by the chairman, Kenneth Allen, the first meeting of the section on sanitary engineering was opened by George A. Soper, who presented a progress report of the committee on air, and suggested that a report outlining the needed work along these lines and summarizing the information at present available, should be published by the association.

L. E. Jackson recounted the progress of anti-mosquito work in New Jersey, where ten counties have expended three hundred thousand dollars in combating the salt marsh mosquito problem. As a result, the work of drainage is about half completed with a total at present of five thousand miles of ditches. Recently much of the ditching has been done with machinery and work is in progress on

new types of machines for digging as well as cleaning the drainage ditches. If the new type of digging machine now under construction proves as efficient as indications promise it will be possible to complete the five thousand miles of ditch still needed in about a year. The new machine will ditch at a cost of less than one-tenth of a cent per linear foot.

The speaker continued by discussing the work done in Hudson County by the use of dykes and pumps to control the mosquito problem over large areas that average a foot less in elevation than the mean low tide. Electrically driven centrifugal pumps are employed to raise the water from the ditches draining the area surrounded by dykes. The combined average capacity of a ten and a twelve-inch pump averages four thousand gallons per minute, the cost being in the neighborhood of thirty-five cents per hour. Mr. Jackson also stressed the need of a cheap and effective larvicide.

The report of the committee on bathing places, presented by George W. Simons, Jr., aroused much interesting discussion. The report recounted the progress in state legislation dealing with these matters and proposed certain standards for the control of swimming pools, based on the amount of excess chlorine and the reaction and clearness of the water, maximum bathing load, temperature, and bacterial count. The advisability of fixing any *Bacterium coli* standard was seriously questioned in the discussion. It was pointed out that health problems associated with swimming pools are in large part related to infections of the eye, ear, nose and throat; that the so-called filth diseases related to the usual use of *B. coli* standards are rarely if ever spread through the water of bathing pools; and that a standard based on the count of organisms producing infections of the eye, ear, nose and throat is the only logical method of control. This latter method is, however, practically impossible at present, due to the difficulties involved in the bacteriological technic required. In Florida it has been suggested (though not made compulsory) that all bathers either wear a bathing cap to protect the ears or use a cotton plug saturated with petrolatum. It is thought that such measures will aid materially in reducing the number of ear infections.

J. Waldo Smith presented a paper on the Becari system of garbage disposal. An eight-cell unit of this type will soon be put in operation at Scarsdale, N. Y. (A general historical and

descriptive article dealing with this system was published in THE NATION'S HEALTH for August, 1923.)

The next paper was by G. W. Fuller and was an account of his observations on European methods of refuse collection and disposal. Following this, Mr. Fuller read a report of the committee on water supply. The use of iodine in the water supply at Rochester, N. Y., as a preventive measure directed against the occurrence of endemic goiter was mentioned as a new development in water supply. (THE NATION'S HEALTH will in the near future present a paper dealing with this development.) Superchlorination to prevent tastes and odors seems to be on the increase. Dechlorination is not popular, apparently because of the added complexity and labor that it introduces. There is obviously considerable advantage in making water inert in relation to pipes and considerable interest has been shown in this problem. In England the hardening of soft, peaty waters seems to be on the increase.

At a final session Langdon Pearse presented a report of the special committee on sludge disposal. This report was a distinctly optimistic one for, although few statistics were presented in regard to the benefits occurring from the use of activated sludge, the report clearly showed that farmers are in the market for activated sludge for fertilizing purposes. That hopes may be entertained for much information in the near future is at once evident since Milwaukee, Chicago, Baltimore, Rochester and Houston are experimenting with activated sludge for fertilizer, as is also the National Fertilizer Association.

G. W. Fuller, in a discussion of this report, described a filter known as a stream line filter which he had seen this summer while abroad which was highly effectual in filtering finely divided colloidal material. It was suggested that this filter might be developed for sludge drying purposes. Mr. Fuller said that by its use sludge could be reduced to a water content of 60 to 70 per cent.

W. H. Frost described studies conducted by the United States Public Health Service on the pollution and natural purification of streams. These studies, which were made on the Ohio and Illinois rivers, were conducted chiefly to ascertain the relation between the degree of stream pollution as shown by laboratory tests and those obvious contributing factors as shown by field surveys. Studies of agar counts at 37 degrees showed marked seasonal variations, the

counts being from ten to twenty times as high in summer as in winter. Dr. Frost is of the opinion that actual bacterial multiplication may take place in the sewers and streams in the summer as well as mechanical breaking up of solids, which might also tend to increase counts.

Counts of the number of organisms made at various points along the Ohio River below Cincinnati's outlets showed that the counts were not at a maximum directly below the outfall but that there existed a phase of increasing counts during the first 10 to 15 hours after sewage enters the river.

The comparison of the curves of bacterial counts for the two rivers indicated that any general law of bacterial death rates in streams will have to include the initial density of bacteria as well as time and temperature among the variables to be considered.

Food and Drugs

The most active development in any branch of public health during the past five years has perhaps taken place in the field of nutrition. Knowledge has vastly increased in regard to foods and drugs, said W. H. Lipman before the food and drugs section, but along with precise study of protein values and vitamin content has come the danger of exploitation of food and beverage fakirs, dietary faddists, glandular panaceas, and the like. Is there no limit to human credulity in regard to false claims for food and drugs? It would seem not, according to Dr. Lipman's examples of flagrant abuses in this field. Education and still more education is the remedy.

An important report was rendered by the committee on problems of canning. A study period of five years has been given to tin plate. Increased coating has proved a distinct advantage for acid fruits and for foods to be kept long in storage. Variations in the composition of steel have been without result, but much progress has been made in processes to eliminate the presence of oxygen, and in handling to prevent deterioration. Reference was made to difficulties arising from a recent order prohibiting in interstate commerce the return of spoiled goods.

The clinical effects of the so-called "moonshine" liquors were treated in a paper by Francis J. Gerty. The type of present poisoning was stated to be alcoholism of an aberrant type; the somewhat different series of symptoms being due not to the toxicity of fusel oil contained in the liquor but

rather to acetaldehyd. Poisoning is very rapid and as a result the patients reach the hospital before exposure is sufficient to predispose to pneumonia. There have been as many cases of alcoholism in the Cook County Psychopathic Hospital during the first ten months of 1923 as were recorded for the entire year of 1922, and alcoholism is now as prevalent as it was before the war and prohibition. Involvement of the kidney and delirium tremens are much less frequent but mental deterioration is common after one or two sprees. The acute cases do not commit crimes for, even when violent, their actions are nonpurposive and the patient can be controlled by those who are familiar with the methods of psychopathic hospital supervision. Cases of delusional insanity frequently result from chronic moonshine alcoholism and it is among the members of this group that criminal acts are committed.

Samuel C. Prescott read a paper on the use of carbon dioxide in foods, in which he stated that fruit and fruit juices were preserved for a much longer time in an atmosphere of carbon dioxide than in an atmosphere of sterile air, though this gas could not be considered a perfect food preservative. The preserving action on protein was similar to that observed with fruits, though to a less degree. It was stated that carbon dioxide offers great possibilities in the manufacture of butter and ice cream and that a good product tastes better in the presence of carbon dioxide but a poor one tastes worse.

A most interesting study of the absorption of *botulinus* toxin was recounted by J. C. Geiger. The investigation was started by the receipt of a sample of home canned corn suspected as the cause of a fatal case of botulism. Examination proved the sample to be the most toxic one ever examined. A letter was then written to the official forwarding the corn for examination and it was found that he had since died of botulism. Since it was not known that this official had either purposely or accidentally ingested any of the sample and epidemiological evidence had previously caused a suspicion that botulism might be contracted by means other than ingestion, animal experimentation was inaugurated for the purpose of studying absorption of the toxin. It was determined that fatal infections of botulism might be caused by absorption through breaks in the skin. The findings indicate that fatal infections gained in such a way might occur in man, though the epidemiological evidence

would indicate that they are comparatively rare.

At the final session of this section, Graham Lusk argued for common sense as well as science in control of the dietary. While meat added to the daily ration of the Italian peasant greatly increases his efficiency, muscular tone does not suffer in those Oriental races who subsist without it. The utilization of the unpalatable German war bread was not aided by a supplementary meat ration. Even dirty conditions of the food and maldorous surroundings are not of themselves conducive to failure in nutrition. "What a man likes best he digests best," said Lusk, and "given a sufficiently wide range of choice, the average individual may be trusted to make a satisfactory selection of food."

Naturally, the results of precise studies on the values of minute quantities of such mineral components as calcium and phosphorus by H. C. Sherman brought out interesting discussion, that while other inorganic substances such as iron and iodine call for future study, the case of calcium and phosphorus is fully briefed. A food supply that is safe should contain of calcium a little more than 0.01 of the protein requirement, and 0.88 gm. of phosphorus per day per kilogram of body weight, the proportion being the same for men and women. Both city and country dietaries are low in calcium. In fact, the average American dietary is short 1 per cent in protein, 4 per cent in phosphorus, and 3 per cent in calcium requirement, stated Dr. Sherman, and calls particularly for the addition of milk and leafy vegetables.

Industrial Hygiene

E. R. Hayhurst, in opening the meetings of the industrial hygiene section, made a plea for the expansion of medical service in industry, stating that less than 5 per cent of the industrial workers of America now have the benefit of systematic medical advice. G. M. Price described the work carried on by pressers in the garment trades as being less skilled than that carried on by clothing operators but more fatiguing, due to the lifting of the heavy pressing irons. These workers suffer mainly from the effects of heat, humidity, carbon monoxide, and prolonged standing. Only robust men usually enter this portion of the industry and the results of Dr. Price's physical examinations revealed the fact that the men in general are in good physical condition. They suffer mainly from bronchitis, gastritis, and infections. The disability rate from

neurasthenia is found to be rather high, 1.9 per cent, and of defective vision, 1.76 per cent. The incidence of tuberculosis was 1 per cent, a figure somewhat lower than that (3.1 per cent) found by Schereschewsky in his study of the garment trades (1915). A contribution of the very first importance made by L. R. Thompson and R. H. Britten on standards of measurement of ten thousand male workers is discussed editorially on another page of this issue.

At the second session particularly keen interest was aroused by B. L. Wyatt's paper on "The Economics of Health Supervision in Industry." Dr. Wyatt stated that health supervision in industry should produce results that will justify the operating overhead in order to add stability and permanence to such supervision; he then discussed the economics of health supervision with an attempt to evaluate the chief factors concerned. Obviously certain factors such as increased production, increased efficiency, diminished urgent claims for compensation, etc., cannot with ease be financially evaluated. Lost time—which is the measure of safety work—may be reduced as much as 95 per cent; a 50 per cent reduction is a conservative estimate. The return from first-aid activities based on services rendered, the speaker said should be placed at between two and a half and three times the amount of the operating expenditures. The medical service need only be considered from one viewpoint, namely the financial value of periodic medical examinations. A number of insurance companies have assembled data to indicate this at a potential life saving value of thirty dollars. Dr. Wyatt used the conservative figure of five dollars. To this must be added forty-five dollars, for each man found to be unfit for employment on medical examination. This forty-five dollars represents the cost of hiring and training a man up to his true productive requirements. Similarly, additional savings are to be credited for each diagnostic laboratory service rendered and lastly by self insurance the employer may provide at a cost equal to that now borne by him for compensation above the following services: Casualty, group health, and group life insurance.

At the final meeting of this section (held at the new building of the Harvard School of Public Health) Professor Cannon discussed the problem of resuscitation in cases of respiratory failure, emphasizing the importance of prompt use of the Schaefer method without waiting for the ar-

rival of apparatus. Drs. Schroeder and Mitchell discussed carbon monoxide poisoning of domestic origin in Baltimore. Out of 145 cases studied 49 were due to faulty appliances and 17 to faulty piping. The marked variations in gas pressure which exist make the problem very difficult to deal with. In discussion Hayhurst reported that of 63 deaths from carbon monoxide poisoning in Ohio eight were due to bathroom heaters. The danger from all such devices is of course greatest in cold weather since carbon monoxide is likely to be given off so long as the gas flame is chilled below the combustion point of that gas. One of the most important papers of the convention was presented by J. C. Aub in summary of the recent studies on lead poisoning carried out at Harvard. These brilliant researches have made it clear that lead normally enters the body in the form of phosphate and is stored in the hard bones. Its subsequent release into the circulation results from any condition of acidosis (due to starvation or an attack of infectious disease) and may be experimentally produced at will by administration of phosphoric acid. Philip Drinker described and demonstrated the apparatus which he has devised for collecting atmospheric dust by electrical precipitation, a device which appears to be the most exact one yet brought forward for dealing with very small particles such as are present in fumes and smokes.

Child Hygiene Section.

The predominant feature of this section was the criticism, constructive and destructive, of prevailing standards of physical rating of children by means of height-weight-age tables.

Maud A. Brown believed that the criteria as used do serve safely to relegate to the malnutrition groups practically all children in need of a special regimen, either medical or dietary. The studies of William T. Porter, however, as yet unpublished but sufficiently extensive and prolonged to give them permanent and unquestionable value, indicate that any estimate of a child's normal or abnormal tendencies must be based not on the "average" child, but upon the "favored" child, one whose heritage, environment, and nutrition may reasonably be conducive to what is really normal, and not stunted or inhibited growth. We do not know what constitutes normal growth, nor have we analyzed its factors. We do know that a good physique is an asset; that underdevelopment is a handicap. Children advanced in school are better

developed than those who are retarded; members of the Royal Society of Medicine are taller and heavier than the common run of physicians; and physicians are of better physique than laborers. Monthly weight taking and the recording height measurements every three months are called for. Dr. Porter's study having to do with several thousand Boston school children over a period of several years indicate that in remedying unfavorable growth variations the height is a safer index than weight. Also, nutrition workers may be needlessly discouraged, or disturbed without grounds, by a failure of children in malnutrition groups to put on pounds, when the fact is that normally two-thirds of weight gained by growing children is put on in one-half the year.

The final session of the Child Hygiene section jointly with Public Health Nursing elicited sharp controversy between the two administrative extremes of school health centering in activities of the teacher, as admirably exemplified in the Virginia scheme, and the more generally advocated school service pivoting on the physician. Arguments pro and con were bandied back and forth, but the scheme that succeeds best, all things considered, was considered best.

The crippled child occupied the foreground in the final papers, R. B. Osgood voicing the orthopedic effort, and Edna L. Foley handling it as a problem of public health nursing. The child is to be corrected as far as may be, trained to the limit of his capacity, physical and mental, the final objective being to salvage a personality and give it the widest opportunity for wholesome and active living.

Public Health Nursing.

Aside from this joint session with the Child Hygiene section, the section on Public Health Nursing held one independent session at which the principal paper was presented by Margaret K. Stack on the requirements for public health nurses in eighty-three cities. The studies here presented indicated that private public health nursing organizations, as compared with those operated by official agencies show better supervision and a personnel of better background in training and experience; but Miss Stack emphasized the fact that if the nurses in a public department were placed under a single nurse director with freedom to organize her staff a result could be attained equal to that achieved by the voluntary agencies. A discussion on the relation of the public health nurse to the practicing

physician was participated in by Ira S. Wile, Alta Dines and Henry F. Vaughan, Miss Dines making a particularly effective presentation.

Health Education and Publicity.

The first session of the section on Health Education and Publicity was devoted to a clinic on printed matter under the leadership of Philip S. Platt. Twenty typical health leaflets and bulletins, issued by official and unofficial agencies, were analyzed in detail by D. C. MacMurtrie from the standpoint of physical arrangement, paper, and typography; and by C. E. Bellatty from the standpoint of presentation of subject matter and psychological appeal. This session proved extraordinarily illuminating and taught the health workers present some very practical lessons.

At the final session of this section, the chairman of the committee on current popular health education material, H. E. Kleinschmidt, presided at a symposium on various educational methods. In speaking of exhibits and expositions, Anna K. Behr stated that health shows as now carried on were largely a hodge-podge. The greatest good will not be attained until exhibits are topically arranged. In regard to the individual exhibits it seems that motion arrests attention; miniature three dimension exhibits are very attractive; but wall charts receive attention only by an unusual person. With exhibits topically arranged visitors should be obliged to follow a definite course or else each group should be accompanied by a trained guide. Marjorie Delavan reported the results of a questionnaire sent to state departments of health. Of the seventeen replying, eight employed a trained writer for their press and news work. Many other interesting facts relating to newspaper publicity were obtained from this source.

Dr. Kleinschmidt, in reporting new methods, told of such means as a Humpty Dumpty circus and parade, and of a folder largely financed and distributed by an ice dealer; the folder prepared by health workers for the purpose of spreading information on the proper means of preserving food during the warm weather. The literature carried no direct advertising but did state ice was cheaper than food or doctor's bills. B. R. Rickards emphasized the need of brevity in the health talks broadcasted by radio and also stated that many were apt to forget that a large percentage of those listening in on such educational material were boys; a fact which should be carefully considered in the prepara-

tion of the material. Printed matter was considered by Evert G. Routzahn and school methods and material by George B. Collins. Ira V. Hiscock indicated the need of a study of health bulletins; a type of educational material which at present has many varieties of form. The class that can be reached by bulletins should be determined and the material prepared for this specific purpose. In reporting its plan of work for the coming year the committee listed such a study as its major consideration.

The Boston Health Show

An important feature of the meetings, though not officially connected with them, was the Boston Health Show held at Mechanics Building, October 6 to 13, under the auspices of the Boston and Massachusetts health departments and the Boston Health Exhibit Committee. In connection with the show there was presented a Historic Health Pageant of an elaborate kind while numerous lectures and clinics were arranged including daily Parenthood Institutes, Baby Health Conferences and various special programs of dancing, gymnastics, etc.

The additional exhibits in the health show were on the whole exceptionally well arranged, each of the many aspects of the modern public health campaign receiving due attention and the contributing agencies being wisely subordinated to the topical presentation. On the other hand, the labels of the exhibits was by no means good and the show lost much of its educational force for lack of clear and forceful exposition of the meaning of each exhibit. Moving mechanical models were numerous and clever.

Among the individual exhibits, special mention should be made of the altogether charming series of models called "The House of Health" in the section on health of mothers and young children and of the valuable demonstration of biologic products made by the Massachusetts State Department of Health. The booths dealing with the health work of the League of Nations and with the newly organized Society of Friends of Medical Progress also aroused special interest. One of the valuable by-products of the health show was the preparation of a directory of Boston's public hospitals and dispensaries, the information for which has never before been gathered together.

The Parent-Teacher Association in the United States now includes in its membership 537,000 persons.

Irish Free State County Councils and Health Reform

At the annual meeting held late in July of the general council of county councils in the Irish Free State, recommendation was made regarding legislative reforms in regard to health. It was considered that the minimum health unit should be the administrative county or county borough, and that every health area should maintain a medical officer of health, a veterinary officer, and an official for the effective inspection of school children. The repeal of the Medical Charities Act is recommended and the provision of powers and facilities to furnish medical benefit to insured persons and their dependents, and medical service for those unable to pay for it.

Though a separate ministry of health is favored, its immediate formation is not urged. Present administration and immediate reforms could, according to the recommendations, be made effective through a council made up of constituted representatives of medical and allied professions, local health authorities, insured persons, labor, and other organizations concerned, and the Ministry of Education.

Disease Incidence Less Under National Insurance

A statement from the Institute of Actuaries, issued to clear up the crisis in England between physicians on the one hand and representatives of medical services to the friendly societies on the other in carrying out the provisions of the national insurance act, it is asserted that during the period covered such a decline in the incidence of sickness among the people has taken place that in most of the large societies it has never been more than 70 per cent, and in some of the years has fallen as low as 50 or 52 per cent of the rate calculated. The improvement is attributed, in the main, to the service of the panel physicians. It is held that the system has secured for a large section of the population medical care of a character and extent never previously obtainable. At a recent conference on the subject of representatives of the panel physicians, it was agreed that the service should be extended beyond the general practitioners range, and that a beginning might well be made with the provision of increased diagnostic facilities, to include Roentgen rays and laboratory service.

American Child Health Association First Annual Meeting

Growth Standards and Health Teaching Constituted the Subjects of Prominence at Detroit Convention

THE First Annual Meeting of the American Child Health Association, held in Detroit October 15 to 17 1923, was attended by more than eight hundred members and guests.

The following were re-elected to office: Herbert Hoover, president; L. Emmett Holt, first vice-president; Livingston Farrand, second vice-president; Thomas D. Wood, third vice-president; Corcoran Thom, treasurer; Philip Van Ingen, secretary, and Edward M. Flesh, comptroller. Maud Wood Park was elected fourth vice-president in place of Grace Abbott who was placed on the executive committee. Other members of this committee are George Barr Baker, James G. Berrien, Clinton H. Crane, Livingston Farrand, Edward M. Flesh, Mary Gardiner, Samuel McM. Hamill, Herbert Hoover, J. H. Mason Knox, Jr., Mrs. William Brown Meloney, Frank C. Page, Edgar Rickard, Richard M. Smith, Philip VanIngen, C.-E. A. Winslow and Thomas D. Wood.

In his address before the opening session of the convention, Herbert Hoover stated that "the physical and moral well being of the nation marches forward on the feet of healthy children." President Hoover spoke of the great benefits that had accrued from the amalgamation of child health organization during the first year of combined effort. The program of the new association was stated to have crystallized along the following lines: (1) the support of demonstration centers to prove the efficacy of scientific organization in child health; (2) the supply of a trained staff to those localities desiring demonstrations and willing to finance them from local resources; and (3) the scientific determination of the standing of different communities in respect to their own efforts in child health promotion.

Courtenay Dinwiddie presented the director's report reviewing progress in the field of child health and citing the great need for continued effort along these lines.

In speaking on the subject of broadcasting the news of child health, Mrs.

William Brown Meloney said, "Knowledge is without influence until it is given to the public. It is without power until it is accepted by the public. One of the longest steps in the progress of the world was taken when that new science known as publicity was developed."

Among the several consequences of good health conspicuous enough to interest the rural mother, Everett C. Hartley listed appearance, usefulness, alertness, and brightness. The endless repetition of the saying that good

them none less than the city mother. Examples of the lack of intelligent supervision given were astounding. In some instances fathers of the rural districts of Arkansas teach their sons to smoke before the youngsters are weaned. "One mother reported nursing her son for eighty-six months and added that he would stop on the back porch and dispose of his chew of tobacco before coming in from school to nurse."

Mary Riggs Noble stressed the far-reaching influence of proper mental and physical supervision during the pre-school period.

"If we have one burning faith among us," said Haven Emerson, "it is that children belong in homes of their own, with other children, and the companionship of their parents." Dr. Emerson urged the abandonment of the idea of the organization of services for children en masse, for provision through private and public institutions and agencies will not carry the load "which must be placed directly where it belongs, upon the family and in the household." Public endeavor has been directed first against the evils of one age group and then against another. Few children have had the benefits of prenatal, infant and pre-school care. "When we see offices set up by parents, staffed by doctors, nurses and others in the parents' employ, engaged in perpetual and continuous education and protection for health, then there will be a beginning of the real, the final, the permanent, the ultimate program for child health."

"Health is a home, household, and family problem except for a few of the situations handled necessarily by the health officer," said the speaker. "We cannot disregard the fact of experience and discontinue our efforts to have good health services available at schools, and for the children before they reach school, but the measure rather of our greatness than our bigness will be the smallness of numbers receiving public care in childhood, the lowness of percentages of children in school with defects, the rarity of expectant mothers who are not pro-

With characteristic verve Dr. George E. Vincent presented to the meeting the essentials of the modern public health movement to be (1) the prosecution of research; (2) the coordination of functions between voluntary and official agencies; (3) the training of personnel; and (4) the closest and most continuous scrutiny of what is doing to discover and correct weaknesses and mistakes.

health is valuable has robbed the truth of its vitality and only by appealing more specifically; stressing the above results, financial saving and freedom from worry, can material interest in child health be aroused in rural districts.

In discussing Dr. Hartley's paper, Frances S. Bradley said that the rural mother, though often losing nearly half of the babies she has borne, loves

Miss Lydia Roberts, assistant professor, Department of Economics, University of Chicago, urged upon the members of the American Child Health Association the importance of psychology and educational procedure in presenting the matter of health.

vided by their husbands with such medical and nursing guidance as physicians now know these women all require."

Stating that three-fourths of the deaf, many of the blind, one-half of the crippled, and three-fourths of those suffering with speech defects became afflicted before school age, Arnold Gesell pleaded for more intensive effort toward the improvement of the mental and physical equipment of the child while it is yet in its formative period.

The second day of the meetings was opened with a symposium on "The Workers in Health Education—The Work They Should Do." John M. Dodson, in speaking of the doctor, said that more care was needed in the selection of students admitted to medical schools, especially as to character and ideals. "More stress must be laid on the training and development of the faculties rather than on the imparting of information. More time should be devoted to first hand training in laboratory and the small group clinic and less to the didactic lecture and display clinic. Most important of all, much more attention must be paid to preventive, as distinguished from curative, medicine."

In dealing with the teacher, Mabel Bragg stressed the teaching of health, citizenship, and the wise use of leisure. Children's activities cannot be curtailed but are rather to be directed along proper lines. If daily inspection

is to be of value it must not be considered as a device for "catching" the children but used as an opportunity of appreciation and commendation of those school children interested in their health.

One of the most interesting sessions of the meeting resulted from the presentation of a paper by Louis I. Dublin and John C. Gebhart dealing with height and weight as an index of malnutrition. The authors presented findings obtained from a study of 1,878 boys and 2,169 girls in the Mulberry Bend district of New York City, one of the largest Italian communities in the country. These children were given careful examination by a well trained pediatrician and classified as well or malnourished on the basis of this examination which considered such factors as the state of the musculature, eye luster, the color and bearing of the child, posture, and the amount of subcutaneous fat, as well as the relation of weight and height to age.

"The first striking fact that came to hand was the marked disagreement in results by the two methods. The physician's careful examination showed 54 per cent of the children to be malnourished. The weight tables with the 7 per cent limit would have selected 12.4 per cent, and with the 10 per cent limit only 6.2 per cent, as requiring nutrition care.

"A method which misses three-fourths of all the children whom a competent physician after a thorough examination would call undernourished has certainly scant value even as a rough index for sorting out the most needy cases."

It was recognized that in this case the children deviated widely from the national type, but, using a norm constructed for Italian children, it was found that only one-half to three-fifths of the children needing care were selected. It was admitted that the height-weight-age standards, though a poor method of examination, is still the best single guide available. Where medical attention cannot be secured it is the only makeshift; it does not give maximum results. "For that there is only one method; to give every child one good physical examination a year. This alone will determine what the true state of health among the children of a community is, and which of them require additional special nutritional care."

Thomas D. Wood said that standards should be based not on the average but on a group of superior children and that immeasurable good had been accomplished by the use of stand-

ard tables, not only in selecting malnourished children but also in interesting all children in health matters. He also said that other methods should be used in addition as far as possible.

Louis C. Schroeder, who examined the children used for the statistical study of Dublin and Gebhart discussed the technique of such examinations.

Opening the sessions of the last day of the meeting, the first paper on the problem of Early Infant Deaths was presented by Edward L. Cornell who showed the lack of specialists in obstetrics. The American Medical Association's Directory lists but 146 purely obstetric specialists in the United States, which gives a ratio of one specialist to 17,000 births. Monetary returns offer a partial explanation for this condition. The average fee for a confinement case is around \$50 while the average fee for appendicitis is \$100. In the former the entire period of care may extend over six or seven months while in the latter the period is rarely over one month. "Educate the public to pay surgical fees for obstetrics and demand expert service," said Dr. Cornell. The social agencies are doing splendid work among the poor in raising standards but the middle class is not touched.

The relations of the public health nurse and the official agencies were treated by Mary Laird and Frances S. Bradley.

The closing session was a joint meeting with the Central States Pediatric Society and the Wayne County Medical Society. At this gathering

Dr. George T. Palmer, director of research, American Child Health Association.

Borden Veeder outlined the three needs of pediatrics; (1) the research worker; (2) the private pediatrician; (3) the pediatrician in public work—outlining the fields and objectives for each type.

Clifford G. Grulee reviewed the growth of knowledge of infant feeding and A. L. Jacoby defined the status of knowledge regarding the mental development and mental hygiene of the child. In a paper on Standards of Growth and Nutrition, Hugh McCulloch pointed out the error involved in placing sole reliance of standard height-weight tables in the selection of undernourished children.

Several round table luncheons were held during the convention. One of the most interesting dealt with the

work of the Manhattan Health Society which is a community organization furnishing supervision for pregnant mothers, assistance at confinement other than the doctor's services, supervision for children under two, and supervision of children from two to six years of age as well as visiting nurse care for sick persons of all ages. Individual membership is \$6 per year; per family of three or more, \$16 per year.

Many of the visitors at Detroit inspected the Merrill-Palmer Nursery School, one of the pioneers along this line in the United States.

A demonstration of Health Education through play, by the Detroit Public School Children proved both interesting and excellent.

Fumes From Type Machines

THERE is still considerable discussion relative to the hazards incident to the printing trade. In former years type-setting was entirely a manual process, whereas at the present time the monotype, linotype, and stereotype have in all large shops supplanted the older methods. There are still many small, old-time establishments, however, in which hand work is carried on exclusively.

In spite of the new methods introduced into the trade, cases of poisoning continue to be too numerous. It has for some time been generally admitted by students of the problem that the more dangerous processes in the trade are those in which the workers are subject to lead dust; melting old type, polishing old type, and setting old type. Those doing stereotyping, electrotyping, linotyping, and monotyping are subject to much less danger, as also compositors working with new type.

The pots of type metal on linotype and monotype machines are kept at a temperature of about 500 degrees C. Since lead melts at about 327 degrees C. and does not boil until a temperature of about 1,525 degrees C. is reached, it has been thought that there is little danger from the metal pots. Fumes do arise, however, when the pot is stirred or skimmed or when replenished with cold pig lead. Particularly on monotype machines, oil dropping on the surface of molten lead produces fumes that are disagreeable if not harmful.

In rooms exclusively devoted to monotyping, the heat from the gas

burners commonly employed to heat the lead pot, as well as incomplete combustion products from the gas may be objectionable. The same gas fumes and heat are experienced with the use of the linotype machine. A new model of linotype machine with an electrical heater has recently been placed on the market. One of these has already been installed in the composing room of the New York Times.

Exhausts for lead pots on monotype and linotype machines are quite universally employed, though their construction presents many difficulties. The pot is hinged to permit swinging out from the machine, hence the exhaust intake cannot be rigidly attached to the main exhaust duct; it must follow the lead pot through the arc of its swing. Branches running from the main duct to the pot usually divide near the pot, one arm receiving the gases from the burner and the other terminating above the surface of the molten lead.

Many machines are equipped with the patented "Zenke head" which is, according to the operators, very satisfactory. A similar report was received from state factory inspectors queried in regard to this. As a test of an efficient condition found in actual operation, the Division of Industrial Hygiene, New York State Department of Labor, has stated that there should be one-half inch static suction generated in the branch

pipe to which a Zenke suction head is attached.

Linotype machines have been quite generally fitted with Zenke suction heads or some other form of double duct based on the same general principle. When this type of fitting was in universal practice, lead in the metal pot was replenished by hand with small pigs. Modern improvements in the method of supplying the solid lead have necessitated further changes. The Margach self-feeding device was introduced. This is an automatic device by means of which a pig of lead, five or six times the length of the small pig previously used, is fed into the metal pot as fast as the molten lead is used up in operation. In some cases when this device was first introduced the branch of the Zenke head over the metal was cut off, thereby negating to a great extent the benefit of the exhaust. To overcome this difficulty hoods were devised that enclose the top part of the pig and the suspending chains. Such hoods, some with the doors open to permit adjustment of the feeding device are shown below, illustrating a battery of linotypes at the McGraw-Hill Company.

Industrial Eye Accidents

Of a total of 1,000 injuries to the eye, statistically studied by Garrow (*Brit. J. Ophthalm.*, Vol. 7, p. 65), 707 were of industrial origin. Metal workers, coal miners and workers in molten metal led the list.

An adequate scheme of ventilation for the protection of linotype machines.

Need for Better Understanding of Injured Employees' Claims

THE application of workmen's compensation laws in forty-two states expresses very clearly the general acceptance of the principle of industrial responsibility for industrial injury, but a survey of the variance in their interpretation shows that widely different meanings attach to questions of personal injury and other accidents. Time must be lost to entitle a worker to compensation and medical appraisal is involved, but there is so much conflict among the administrative laws of the different states, and such lack of facilities for getting information on the questions involved, that the National Industrial Conference Board has undertaken a study which is a new contribution to this vital problem, receiving in its work the active cooperation of the Conference Board of Physicians in Industry.

What is needed most, in the opinion of the experts, is greater consideration of the opinion of medical men in the administration of workmen's compensation laws, and more uniform practices among those concerned with their administration. Identical injuries are compensable in widely varying amounts in various states, and a similar inequality exists in the courts' interpretation of identical sections of various laws.

The only states which have no workmen's compensation laws are Arkansas, Florida, Mississippi, Missouri, and North and South Carolina. The experiences of the other forty-two states have now been sufficiently extended, in the opinion of the National Industrial Conference Board and its research staff, to render the record of the physician's part in workmen's compensation laws worthy of being permanent.

There is an increasing tendency to give due consideration to the value of adequate medical treatment in the administration of the laws. Early in their administration, the doctor's part received scant attention. In some states, even for the most serious injuries, only two weeks' medical treatment could be legally provided. "A period of experience has now elapsed," says the report, "sufficient to enable those who make the laws and those who administer them to obtain a better view of the problem. Such expe-

rience has shown the advisability of greatly increasing both the time and amount of medical service rendered, until at this time in 20 states such service may be unlimited."

The report shows that employers, for failure to report accidents to their men, may be fined various amounts, ranging from ten dollars in California, Delaware and Illinois to a year's hard labor in Alabama or \$2,500 in West Virginia.

The term "medical service" receives widely different interpretations in various states. Ohio and Connecticut have freed employers from liability when injured workmen took their troubles to quacks, masseuses and "doctors of medical electricity." Similarly the California State Commission refused to reimburse a worker who consulted a Chinese herb doctor. Iowa and Connecticut do not regard osteopaths as qualified to act in compensation cases, while California permits them. In Wisconsin Christian Science treatment may be resorted to by an injured worker with his employer's consent. There a death from a bruised shinbone infection which was treated by prayer was held compensable. However, a Boston elevated railway employee who presented a fourteen dollar bill for services by a Christian Science practitioner lost his claim.

One result of many of the laws has been to break down the universally accepted principle of privileged communication between doctor and patient. In many states physicians can be compelled to testify as to their treatment.

States differ in the law's rulings on various surgical operations. For instance, the hand extends to the elbow in the legal opinion of Alabama, Connecticut, Delaware, Kansas, Nebraska, New York, and other states, while it extends only to the wrist in Colorado, Idaho and Montana. The human foot in Colorado extends only to the ankle, but in Alabama it extends to the knee. New York takes a middle ground, merely qualifying it as terminating some place "between the knee and the ankle." A Pennsylvania worker lost the power in one foot to walk easily and received compensation, while in Minnesota the Supreme Court refused to affirm a similar award because

"the foot was still there," but authorized partial compensation.

Various state courts and commissions have answered in various ways the question: "What is the human body worth?" For example, a thumb is worth \$225 in Wyoming, \$600 in Oregon, and in New York and Alabama the legal compensation for sixty weeks. Wyoming holds a human hand worth \$1,000, while its value rises to \$1,600 in Washington, \$1,900 in Oregon and 244 weeks' compensation in New York, and it is worth 104 weeks' compensation in Colorado. Similar variations in legal value occur with reference to the loss of an eye, a toe, a foot and fingers.

New York holds that when a worker is injured so that only his good looks are impaired, he may collect from his employer owing to the humiliation entailed. In New York and Michigan compensation was awarded when horses bit off ears of workers, but in New York the award was based on the common law. One worker collected in New York because he was unable to replace his lost eye with one of glass, and a drooping eyelid which made the injured person appear to be winking at whatever he observed, resulted in another award. Another New York workman, whose nose was bitten off by a horse, received \$2,500 from the compensation board. Deafness has been valued at \$3,000 in Oklahoma, and deafness in one ear at \$1,500. In Washington loss of hearing is only compensable at \$1,900 and of one ear's deafness at \$500.

Pennsylvania has held in the case of an automat lunch-counter attendant, that heat prostration at work causing death was an accident, while in Connecticut frostbite was similarly judged. In New York, however, the courts held that a sunstruck brewery wagon driver was not entitled to compensation. Pennsylvania authorities showed regard for the injured worker in the case of a dogcatcher in New Castle, who was bitten by one of his captives and died of hydrophobia. His estate received compensation.

Persons bitten by insects, when spotted fever has resulted, are not entitled to damages in the opinion of the Idaho Industrial Accident Board. However, New Jersey authorities held that a chef pinched by a lobster was

entitled to five weeks' disability award for infection. In California, on the other hand, a farmhand, bitten on the leg by a spider, failed to get damages. The same commission, however, reversed this ruling in the case of a sailor whom a spider bit, holding that spiders had no business aboard ship and that the ship's owner was liable. Poison ivy injuries have been held compensable in New York and Massachusetts, but a municipal laborer in San Francisco was denied an award for poison oak injuries.

One of the sharpest controversies among compensation boards is over the proper valuation of the impairment of sight. Various tables and tests have been evolved, but they display wide discrepancies. They agree, in fact, only on one item: What constitutes normal vision?

Montana, Idaho, Utah and Wisconsin allow twenty weeks' more compensation for the removal of an eye than for blindness in one eye without removal. Pennsylvania, however, holds that where there is blindness the removal of the eye makes no difference, and allows nothing additional.

One of the most important phases of the report is that which shows the widely varying amounts expended for medical treatment under the awards of various states. For instance, in Wyoming in one year allowed only 3.6 per cent of the total awards as for medical expense, while the percentage in Connecticut for two years was 38.2, totaling \$1,663,107.08, and in Massachusetts, where industrialism has reached one of the highest points of development, the percentage was 20.8 with medical expenses of \$1,602,057.74.

In only one state, New Mexico, is there a provision for the physical examination of workers before an injury occurs.

Summing up its investigations, the report shows that both interested parties to compensation laws, the workers and the employers, have accepted as just, the principle that one group should be charged with major responsibility for injuries suffered by another group. Differences which have appeared are not of sufficient importance to cast doubt on the value of the work as a whole, the report concludes.

House Letting and Infection: A Reading of English Law

Much interest has been excited by the publication of the *Lancet* of July 7 of Mr. Justice McCardie's reserved judgment in the case of Col-

lins vs. Hopkins, the issue of which was the extent of the implied warranty by the lessor of a furnished house that it is reasonably fit to inhabit, where there has been an infectious disease in the house shortly before the lessee's occupation, the disease in this case having been tuberculosis.

In his reading of the law a warranty is implied in any contract on the lessor's part that the premises are reasonably fit for habitation. The law does not lay upon the lessor the obligation to consider the fads of nervous persons unreasonably afraid of infection where no danger exists, but it does include freedom from risk of infectious disease, regardless of whether the subject was mentioned between him and the tenant or not. The judgment in question allowing damages to the tenant was definitely based on the fact that the house was left in a dirty condition, and that dirt affords a nidus for development of bacteria of all kinds and over and above this there was the assurance on the part of medical attendants that the case involved was not one of pronounced symptoms of advanced disease; the patient was sanatorium trained, and meticulously careful. Hangings and floors were washed, bedclothes sent to the laundry, and new covers made for cushions, etc., etc.

The *Lancet* makes the point in commenting on the case that "if the patient was carefully trained in his habits, if he carried out all his instructions, and if due regard was paid to ventilation, sunlight, cleanliness, removal of dust and dirt, and the like, then the risk of infection might not be serious even to those who resided with him. Still less was the risk to those who entered the house after the patient had left, the essential factors in the conveyance of disease being the conveyance of infection from one person to another."

The whole potency of methods of disinfection of the modern hygienist is brought up in the connection. Dr. T. W. Naylor Barlow is quoted as saying that all house infection may safely be scrapped. Without denying the possibility of transmitting disease by means of inanimate objects, he denies the role of books, the walls of rooms, and such like in the spread of disease and declares that the so-called disinfection of rooms by gas is futile and unscientific. Conviction is growing that the living, breathing human being is the only danger, and the essence of hygiene is to organize bed-

side nursing during the whole course of a patient's illness in such a way as to make terminal disinfection of secondary importance or, indeed, altogether superfluous.

It is perpetuation of the chronic carrier to which professional and public alike should be directed and, while gaseous disinfection by formalin and sulphur fumigations may be done, this sanitary ritual should not lead to any neglect of the weightier matters of the law of personal hygiene, soap and elbow-grease, sunshine, and ventilation.

Health Topics at World's Dairy Congress

The program announced for the World's Dairy Congress which was held in Washington, D. C., October 5 to 10 was arranged in four principal sections:

(1) *Research and Education*: to interest teachers, investigators, engineers, and other technical men interested in the solution of dairy problems.

(2) *Industry and Economics*: to benefit men engaged in breeding dairy cattle and in producing, manufacturing, exporting, importing, storing and distributing dairy products and equipment.

(3) *Regulation and Control*: to serve national, state, municipal, and private officials concerned with standards, adulterations, sanitation, and animal disease control.

(4) *National Health*: to coordinate interrelated problems of public health and nutrition workers, philanthropists, social and welfare workers, and students of the influence of diet on the health and vigor of nations.

The exchange of experience from the representatives in this field from all nations, and especially the radical departure of this from preceding programs in supplying adequate research into health and economic backgrounds, should enable the Conference to render inestimable service.

Athens, Ga., has been selected by the National Child Health Association for a five-year child health demonstration. A fund of \$250,000 has been set aside by the Commonwealth Fund for conducting this center, which will be established within a month with a maternity clinic, as the initial step, to be administered by experts. The personnel will soon be increased by the addition of physical educational workers and specialists in the diseases of children.

LATE HEALTH DECISIONS IN THE COURTS

By DOROTHY KETCHAM, UNIVERSITY HOSPITAL, ANN ARBOR, MICH.

THE Supreme Court of Massachusetts recently passed upon appendicitis as a complicating factor. The employee in question received an injury to his back caused by falling from a stepladder and which arose "out of and in the course of employment." The injury either caused or aggravated an arthritis of the spine which totally incapacitated him until the time he died. During this period compensation was paid. February 4, 1922 he suffered from severe abdominal pains diagnosed as appendicitis, he was operated therefor, and died ten days later. The widow sued for compensation but the Court states that "As the appendicitis had no connection between the injury and the death, it could not properly be found that death following the operation resulted from the injury. The appearance of appendicitis, necessitating an operation which resulted in death constitutes a new and intervening cause wholly independent of and without any relation to the injury and the death, the latter could not be found to have resulted from the former. The operation was an independent intervening agency which broke the chain of causation."—*Up-hams Case*, 139 N. E. 433.

THE Supreme Court of Illinois June 20, 1923, decided that where an employee died from a disease which was aggravated or caused by an injury received in the course of his employment, it may be said that death resulted from the injury. The two physicians who performed an autopsy on a deceased employee did not agree as to the probable causes of death from hypostatic pneumonia and meningitis. However, they both agreed that the accident might have been contributory. The Court held that the findings and award of the Commission "are not against the manifest weight of evidence . . . Where an employee dies from a pre-existing disease and the disease is aggravated or accelerated by an accidental injury, or an injury which produced pneumonia or other disease

which aggravated or accelerated such pre-existing disease, the death may be said to be caused by accidental injury." It may be added that syphilis was found to be a complication which one of the physicians felt caused the hemorrhage of the brain. This physician admitted on direct question, however, that "the accident might have been a contributory to his death, and that the autopsy showed a hypostatic pneumonia, which might have been one of the causes of his death . . ."—*Great Lakes Supply Company v. Industrial Commission*, 140 N. E. 2.

ON September 28, 1918, the plaintiff filed suit to recover damages for an occupational disease, namely, lead poisoning, caused by continuous employment for about a year and a half in a place laden with dust and fumes, where he contracted the disease. The Court holds that cases arising prior to 1921 when the occupational disease law was enacted are not compensable and recovery at common law for diseases of that character would seem to be denied.—*Bajackuck v. Willard Storage Battery Company*, 140 N. E. 405.

A SERIES of cases recently decided by the Massachusetts Supreme Court brings up the matter of medical services and hospital treatment. In the first two cases the injury admittedly arose "out of and in the course of the injured man's employment, each being entitled to necessary treatment beyond the two weeks waiting period as unusual cases. Paul Rys was injured May 17, 1921 and was treated at the Haymarket Relief Station. From May 19 to September 28 he was treated by Dr. Frederkiezicz at his office except on May 31 and June 1 when one finger and a portion of another were amputated. The Industrial Board found that his was an "unusual case" entitled to prolonged care. The insurer claimed that it was not an unusual case and that the Board was not warranted in holding it liable for medical services.

"The term 'unusual case' as used by the Legislature, according to the Court, was adopted at the request of the Industrial Board to distinguish as follows: It is manifest that the Legislature did not intend to impose all expenses of medical attendance upon the insurer. The obligation to provide such attendance as an absolute duty is confined to two weeks after injury . . . It is not in an ordinary case requiring longer medical attendance that the discretion of the Board may be exercised to charge this attendance to the expense of the insurer. It is only in 'unusual cases' that they may do so." The Court states that in this term would ordinarily include "major operations, spinal injuries calling for special apparatus, and serious injuries to the eye or brain demanding the services of specialists. It is equally clear that the statute is not applicable to the minor injury, even though treatment for more than two weeks is necessary."—*Rys' Case*, 139 N. E. 507.

THE Supreme Court of Wisconsin recently passed upon the compensability of hernia and treatment for same. The Court states that the mere fact that a hernia developed during the period of the man's employment is not sufficient to show any relation between his employment and his condition. It was also contended that the Industrial Commission had no jurisdiction to enter an award requiring the company to offer to the applicant medical, surgical and hospital treatment. "While under the terms of the act the employee shall have the right, in event of the failure of the employer, to tender medical treatment, to procure the same, and to be re-imursed therefor, this certainly does not confer upon the Commission the power to compel the employer to offer the treatment in the first instance or prescribe its character or extent."—*Belle City Malleable Iron Company v. Industrial Commission*, 192 N. W. 1010.

THE Occupational Disease Act of Illinois amended in 1921, p. 444, has been declared unconstitutional for failure to insert the amended section at length in the new act and because of an attempt to amend the existing law by not properly distinguishing new and different portions from the older ones.—*Kelley v. St. Louis Smelting & Refinery Co.*, 138 N. E. 618.

SANITARY AND HYGIENIC ADVANCE

Anthrax in Australia

The first case of anthrax infection of man to be reported in Australia was in 1917. Since the report of this case 32 others have been added to the list. Of the total 33 cases on record 31 occurred on the shaving area; 2 on the forearm were traced to infected goat-skins. In 15 out of the 31 cases in which the portal of entry was on the shaving area of the face, anthrax bacilli were recovered from the patients' shaving brush. In 6 cases anthrax bacilli were recovered from brushes of the same type though not from the patient's brush. In five cases anthrax bacilli were not recovered on the examination of brushes and in five cases no examination was made.

The great majority of infected brushes have entered Australia in consignments from Japan. When human anthrax first appeared in Australia, a proclamation prohibited the importation of brushes from certain countries, subject to specified conditions. Later this ruling was mitigated to permit the entry of goods if a certificate of disinfection was produced within 60 days. Later, because of the occurrence of several fresh cases and the unreliability of the certificates, absolute prohibition of importation from certain countries was substituted.

This prohibition was removed when the Japanese Imperial Government agreed to guarantee disinfection and issue the certificates. Since this action was taken no case of anthrax has been traced to imported brushes. Other countries must still comply with approved disinfection measures. (*Health, [Melbourne] March, 1923, i, 3, p. 75*).

Detection of HCN

Poisonous hydrocyanic acid gas is sometimes evolved in dangerous quantities from cyanides used in metallurgical and chemical operations. This gas is much used for fumigating buildings, ships, greenhouses, and such commodities as grain and cotton to destroy rats, mice and insect pests. Wherever cyanid fumes are evolved, thorough ventilation is nec-

essary in order to render the surrounding air safe to breathe. Many persons have been killed by entering tanks and fumigated places too soon.

In view of the need for a simple test for the detection of these gases, Katy and Longfellow, at the Pittsburgh experiment station of the Bureau of Mines, conducted a series of experiments which resulted in the development of color test papers for detecting hydrocyanic acid gas vapor. The shade of color produced in tests, compared with a color chart, gives an estimation of the concentration of the hydrocyanic acid gas over a range of 25 to 1,000 parts per million parts of air. The investigators' determinations in the laboratory were within 20 per cent of those found by chemical analysis. It is recommended that unprotected persons be not allowed to enter atmospheres containing hydrocyanic acid gas unless tests show concentrations not exceeding 100 parts per million. (*Serial 2504, Bureau of Mines*).

Phagocytosis of Lead

Using Fenn's "film method" for studying phagocytosis, Fine has determined that metallic lead is less readily phagocytized than is basic lead carbonate. The injury of leucocytes by soluble lead is shown by their diminished ability to engulf carbon particles. This toxic effect of soluble lead is also the probably explanation of the diminished phagocytosis of carbon in the presence of metallic lead. The rate of phagocytosis of metallic lead is of the same low order of magnitude as that of quartz.

The fact that lead compounds are phagocytized more readily than metallic lead may offer an explanation of the fact that laborers inhaling basic lead carbonate and other lead compounds are relatively free from tuberculosis, but suffer from lead poisoning; whereas printers who inhale metallic lead dust, show a high incidence of tuberculosis but are relatively free from poisoning. This theory would also include the fact that metallic lead acts somewhat in the manner of quartz, in producing

fibrosis. (*J. Indust. Hyg., Aug. 1923, v. 4, p. 138*).

Problem of Epidemiology

Hone, the chief quarantine officer of South Australia, states (*Health, June 1923, i, 6, p. 153*) that during the past five years a series of acute cases of an unrecognized illness have been observed in and around Port Adelaide. The first cases were looked on as aberrant cases of typhoid or paratyphoid infection. Later more cases appeared among men occupied on weevily wheat stacks, so that the disease was called by the wharf laborers the "wheat disease." One of these later cases died and post mortem showed no intestinal ulceration.

Early symptoms simulate typhoid very closely, but serological examination is invariably negative. Cases having a severe rash have been taken for measles. Blood from the patients invariably agglutinates *B. proteus* after the eighth or tenth day, in dilutions from 1-80 to 1-10,000. Clinically and serologically the resemblance to typhus is marked, but body lice have never been found on a patient and head lice only once.

It is thought possible that this disease may be quite wide spread in Australia since the condition is very easily confused at varying stages with typhoid, measles, and typhus. Investigation of the problem continues.

Agitation of Scum in Imhoff Tank

To prevent "boiling over," apparatus for the mechanical agitation of scum in the vent chamber of an Imhoff tank has been installed at Newton, Kan. The mayor of Newton and a local machinist devised a walking-beam arrangement carrying four mill-conveyor screws upright in the vent chamber. Power is derived from one of the sewage pumps. An engineer of the firm designing the plant states that such satisfactory operation has resulted that a similar arrangement has been installed in the plant at Enid, Oklahoma. (*Eng. News-Record, Aug. 23, 1923, 91, 8, p. 301*).

The Mississippi Valley Conference on Tuberculosis is to be held at Evansville, Ind., October 8 to 10. Dr. Robert G. Paterson, executive secretary of the Ohio Public Health Association, is president of the conference.

Typhus Immunity

Weil and Breinl have shown that the injection of 5 c.c. of immune serum into guinea pigs, followed on the next day by an intraperitoneal injection of 0.001 of an emulsified typhus infected brain produces immunity in the animal so treated. This can be shown by reinfection 8 weeks later which fails to produce symptoms of the disease.

The investigators state that their method "consists in incorporating immune serum and virus into the organism at the same time in such proportions that the infection, i.e., the development of the virus, is not prevented, but that the infectious symptoms alone are suppressed. How far it will be possible to use the experience gained in animal experiments for the immunization of man must be left to future investigations to settle." (*J. Infect. Dis. July 1923, 33, 1, p. 60.*)

The After-Care of Poliomyelitis

In the beginning, the supervision of poliomyelitis cases in Vermont was purely surgical. Then was added after-treatment by a trained field worker. The scope of the field work was enlarged, and the worker investigated cases throughout the state needing treatment, instead of waiting for the patients to be brought to the clinics. A definite plant for handling operative cases was instituted. A school for crippled children was founded. A department of vocational training was established. After eight years of experience in the work Robert D. Lovett, (*Journal A. M. A., Sept. 15, 1923, 81, 11, p. 921*) presents his personal conclusions as to its value and estimates what has been accomplished. It seems evident to him that the number of disabilities from poliomyelitis has been greatly diminished, and the number of serious resulting deformities is considerably smaller than it would otherwise have been; that the patients have been, on the whole, appreciative and cooperative, and that many are now independent, useful citizens, capable of self-support, who otherwise would have been severely crippled if not quite helpless. In other words, from being chiefly a surgical problem, the work has become largely a problem of supervision and after-care. Immediately after an epidemic and for two or three years more, the problem is an acute surgical one with definite requirements in the way of effective following up in the homes. After three or four years, the surgical ele-

ment becomes less insistent and the follow-up work more so. The study of poliomyelitis seems to indicate that the disease is a periodic one, and, until more is known about the way in which it is transmitted, there is reason to believe that Vermont may be the scene of future epidemics. If this should be the case, the presence of an effective organization such as now exists is a real insurance, as it could be expanded to meet an emergency.

Oxygen-Oil Explosions

A study of the nature and causes of oxygen-oil explosions is being conducted at the Pittsburgh experiment station of the Bureau of Mines. This problem was taken up by the bureau as a result of the oxygen explosion at the Jefferson Physical Laboratory of Harvard University, and other similar explosions, in order to supply technical information which would serve as a basis for safety precautions in the future. At the Harvard inquiry the fact was emphasized that the limiting pressures and temperatures above which compressed oxygen and lubricating oil are capable of spontaneous explosion are not known. The problem is also of importance to the Army and Navy and to the Bureau of Mines in connection with the hazards incurred in the use of compressed and liquified gases in the re-purification of helium. In fact, the risk of fires and explosions due to traces of lubricating oil coming into contact with high pressure oxygen is of serious interest to all concerned with the manufacture and use of oxygen, a commodity which is now being produced and distributed on a rapidly increasing scale. A preliminary report, by Hersey, giving a general outline of the problem and a summary of results to date, is now available. (*Serial 2507, U. S. Bur. of Mines*).

The Potassium and Calcium Balance in Cancer

Wolf (*Compt. rend. Acad. d. Sc., Vol. 176, p. 1932*) confirms and extends the work of previous experimenters in regard to the abnormally high proportion of potassium as related to calcium in cancerous tissue and the effect of such an excess of potassium in increasing permeability of the cell membrane and thus promoting the development of the diseased condition. The use of ionic calcium in the treatment of cancer seems to the author to be clearly indicated.

Garbage Bills Collected by Agents

Bills for the collection of garbage from the householders of Sacramento, Calif., are presented by agents of the city. With occasional aid from the head of the department, three collectors have been found adequate to collect from the 15,000 places that subscribe to the garbage removal service. (*Eng. News-Record, Aug. 23, 1923, 91, 8, p. 307.*)

"Solicitation in person is made rather than mailing the bills because that additional cost is more than offset by the lower percentage of bad bills. Another advantage of personal solicitation is that the collector can report attempts to evade proper classification, failure to observe sanitary regulation, etc."

Carbon Tetrachlorid Fire Extinguishers

Tests made by Katz, Gleim and Bloomfield at the Pittsburgh experiment station of the Bureau of Mines relative to the hazards to fire fighters from gases and smoke resulting from the application of carbon tetrachlorid extinguisher to electric arcs, burning insulation, or fires such as may occur in electrical apparatus and machinery. (*Serial 2499 U. S. Bur. of Mines*).

It was found that the application of one cubic foot of carbon tetrachlorid fire extinguisher to electric arcs and burning insulation in a chamber of 1,000 cu. ft. capacity developed phosgene, chlorin and hydrogen chlorid in quite dangerous concentrations. Carbon tetrachlorid vapors, sulphur dioxide and carbon monoxide were also formed in less dangerous concentrations. Rats exposed for 15 minute periods to the gases evolved from the use of carbon tetrachlorid on the arcs died or were seriously affected.

So far as is known, carbon tetrachlorid extinguishers are the most effective and satisfactory of any that can be applied to electrical fires with safety from shock to the operator. Arcs of 60 amperes direct current and 220 volts and 35 amperes and 500 volts were easily extinguished with a 1 quart carbon tetrachlorid fire extinguisher.

It is not the purpose to discourage the use of carbon tetrachlorid extinguishers which are safe under all conditions excepting those in close confinement of fire gases in absence of ventilation and lack of ready escape for the operator from the gases.

Movement of B. Coli in Ground-Water

A report of the progress of the Board on Excreta disposal has been made by Stiles and Crohurst. (*Pub. Health Rep.*, June 15, 1923, 38, 24, p. 1350).

Pollution with fecal *B. coli* has been followed in the ground-water for distances up to 65 feet from the trench in which the pollution was placed. Uranin has been recovered from the same wells and has spread, to a maximum distance of 115 feet from the pollution trench. The pollution traveled this distance in a period of 187 days. No convincing evidence was found indicating that the pollution travelled against or at right angles to the flow of the ground-water.

The pollution travelled only in a thin sheet at the surface of the zone of saturation. As the ground-water level falls in dry weather the pollution tends to remain in the sand above the new (lower) level.

The soil in which the measurements of speed and distance of pollution travel were made, was a fine sand with an effective size of 0.13 mm.

A Vaccine Against Acute Conjunctivitis

Nicolle, Conseil, and Cuénod (*Compt. rend. Acad. d. Sc.*, Vol. 177, p. 382) have demonstrated that subcutaneous injections of killed cultures of the Koch-Weeks bacillus will confer complete protection against the conjunctivitis caused by that organism.

The Fauna and Flora of the Imhoff Tank

It is a long time since much of importance has been added to our knowledge of the fundamental biology of sewage treatment processes. The careful cooperative study recently undertaken by the Agricultural Experiment Station and the Department of Health of the State of New Jersey at New Brunswick is therefore of the first importance. A preliminary report by Hotchkiss & Murray (*Am. J. of Pub. Health*, July 1923, VIII, 7, p. 562), presents suggestive data in regard to the distribution of the various types of bacteria in the Imhoff tank treating the sewage of Plainfield. This work was conducted by the dilution method using media calculated to reveal the presence of groups of bacteria exhibiting certain definite biochemical properties and shows very clearly the distribution of various

groups of proteolytic, nitrifying and denitrifying forms. Organisms producing ammonia from pepton and liquefying gelatin are present in enormous numbers. Denitrifiers as would be expected increase in the tank and nitrifiers decrease slightly although the number of nitrifiers present throughout the process is rather surprising. A second paper by Hausman (*Am. J. of Pub. Health*, August, 1923, VIII, 8, p. 656), discusses the protozoa present, mainly small flagellates of the Monas type and small ciliates of the Colpoda type.

Garbage Disposal for Buffalo

From an analysis of bids on various single and combined methods of garbage disposal, received last year by the city of Buffalo, H. P. Eddy has recommended that a choice be made between garbage reduction by the Cobwell-Merz process and a piggery supplemented by a garbage-and-manure drying plant (Wannenwetsch). Based on the estimated population for 1935, the approximate cost of the reduction plant would be \$775,000, and the cost of the combined piggery and drying plant, \$779,000.

The city is warned that they must not overlook the fact, as has so often been done, that efficient operation is as essential as correct design and construction. (*Eng. News-Record*, Sept. 30, 1923, 91, 12, p. 479.)

Bacterium Aerogenes in Swimming Pools

A study of gas forming organisms in samples of water from two swimming pools has been reported by Levine and Werkman. (*J. Am. Water Works Assn.*, July, 1923, x, 4, p. 620). It was found that gas forming organisms when present were usually of the *Bact. coli* type in the pool used exclusively by men, whereas the organisms found in samples from the pool used exclusively by women were practically always the *Bact. aerogenes*.

The women's pool was situated in the basement; there was no provision for visitors, and no arrangement to prevent the tracking in of street dirt to the runways around the pool. The men's pool was located on the first floor, had a visitor's balcony, was lighted by high windows that are seldom opened, and was so arranged that it is practically impossible to track dirt to the edge of the pool.

Changes in the arrangement of the women's pool so that it is practically impossible to track in street dirt or mud resulted in the almost complete elimination of *Bact. aerogenes*.

Influence of Suspending Medium Upon Thermal Death Point

An important point is brought out by Fleischer and Amster (*Ztschr. F. Hyg.*, Vol. 99, p. 209) who have studied the length of time for which colon bacilli remain viable at 52° C. in various suspending media. Sugars, gelatin, pepton and various tanning compounds promote a longer viability while weak alkalies and concentrations of various salts in about tenth normal strength markedly reduce it. The differences are sufficient to indicate the need for great care in thermal death point studies. Thus in one experiment the bacteria survived for 50 minutes in distilled water, for 40 minutes in NaCl, 30 minutes in KCl, and only 10 minutes in CaCl₂ and MgCl₂, all the solutions being of tenth normal strength. In another test, the bacteria survived for 60 minutes at pH 5.0 and 6.0 while the survival time fell to 45 minutes at pH 7.1, to 30 minutes at pH 7.5 and to 10 minutes at pH 8.0.

Effects of Splenectomy on Tuberculosis

Splenectomy in rabbits followed by intravenous injection of tubercle bacilli causes definite changes in the distribution of bacilli and the lesions they produce according to investigations carried on by Foot. (*J. Exp. Med.*, Sept., 1923, xxxviii, 3, p. 263).

Pulmonary lesions are fewer and exhibit a larger number of polymorphonuclear leucocytes and contain as a rule more bacilli than do those of controls. Lesions in the liver are more numerous and destructive in splenectomized animals than in controls. There is not such a marked difference in the kidney but the tubercles are fewer and less well developed in the splenectomized animals.

The course of the disease is not affected materially by splenectomy, if anything it is slightly more rapid. The extra involvement of the liver more than offsets the decreased pulmonary infection.

Plans for the care, cure, and education of crippled children of the world—of whom it is estimated there are more than three hundred thousand in the United States alone—were laid before the conference in Elyria, O., September 25, of the International Society for Crippled Children. Delegates to the conference represented twelve states and two provinces of Canada.

HEALTH PUBLICATIONS REVIEWED

The Doctor Looks at Literature

The literati have not been enthusiastic about Joseph Collins' "The Doctor Looks at Literature." Critics of the book speak of his "attempt" at interpretation of modern fiction, and make light of his literal estimate of artistic values.

But no one, author or otherwise, likes the photograph of his own soul. What surprises the modern realistic writer is that what he is pleased to call the mirror of life may by others be held more strictly as documentary self-revelation. "Those who are experienced with the insane give great diagnostic weight to their writings, not only the orthography and the syntax, but the sequence of thought, the rhythm, the continuity of narrative, the pertinency of reference, the discursiveness of the narrative, and the way in which the writer develops and finally presents the central thought or idea." Why then should not the psychiatrist be permitted to apply this test of sanity to modern fiction writing, and why, if the emotional content persists instead of showing the normal tendency to return to a state of equilibrium, is it to be regarded genius in a writer and mere perversion in the man of the street?

Dr. Collins does not say that psychology is not the province of fiction writers. The warring of instincts and complexes he considers the very stuff out of which drama is builded. Well wrought studies of integration and disintegration take the highest rank in fiction. Even the literary contribution of a disordered mind may be of the highest value. Dostoevsky—an epileptic himself—is a master of portrayal of madness and bizarre states of the soul; Proust, master psychologist and novelist truly interprets the laws governing associative memory; the diarist group, excellent examples of shut-in personalities, none the less present invaluable gems of subjective thought. If, however, such authors as Joyce insist upon depicting a chaotic world in which no decent person would desire to live, and D. H. Lawrence is as ribald as he thinks his public will stand for, that is the other side of the effort of egocentric genius to force the world to its own individual viewpoint.

"The Doctor Looks at Literature"

is an interesting contribution. It presents a fresh viewpoint of the works of James Joyce, Fedor Dostoevsky, Marcel Proust, Katherine Mansfield, Rebecca West, Stella Benson, Fredric Amiel, Georges Duhamel, D. H. Lawrence, and J. St. Loë Strachey. Collins' own preference is for sane statement, coupled with rhythm and style. If he is impatient with the claims of incoherence, and with attitudinizing instead of honest confession, that is his right. The book is recommended.

George H. Doran Company, 1923.

Health Training in Schools

Miss Theresa Dunsill has prepared for the aid of teachers, nurses and other educational health workers an admirable series of outlines of health teaching for the grades with a long list of health stories to be used in interesting the children (selected from many sources) with detailed discussions for games and exercises and a series of definite projects useful in the teaching of the principles of cleanliness, the care of the teeth, nutrition, safety and the like. The Modern Health Crusade is basic in the plans outlined, but a wide variety of sources have been quoted and the book is supplemented by an excellent bibliography. It should be in the hands of every teacher of health.

National Tuberculosis Association, 1923.

The Worker and the State

Professor Frank Tillyard of the University of Birmingham has presented in this volume an altogether admirable review of British legislation bearing on industry. After a general survey of the relations of employer and employee under the common law and of the experimental fashion in which statutory legislation has been developed in this field the author reviews in detail the interference of the state in regard to wage payments, the complete and partial prohibitions of work (for children, both women and young persons and both adult males in dangerous employments), the regulations dealing with the safety of the worker and the regulations dealing with the health of the worker. The book is in

no sense merely a catalogue or topical summary but a reasoned philosophical discussion of the principles involved, enriched by numerous illustrations of actual cases which indicated the spirit in which the law has been interpreted. This spirit particularly as evidenced in the decisions of the House of Lords, the ultimate court of appeal, has been in the main characterized by a remarkable combination of wisdom and liberality. While the book is thoroughly readable it does, however, give the reader in the main a very complete picture of the past and present status of legislation in all the fields covered and the book will prove illuminating to every American worker in this field.

E. P. Dutton, New York, 1923.

Outlines of Medical Zoology

In this small book of 175 pages the three authors, R. W. Hegner, W. W. Cort, and F. M. Root, discuss respectively the protozoa parasitic in man, the worms parasitic in man and arthropods of medical importance. The book is far too technical to serve as a general introduction to the subject and it seems too condensed to be of very great value as a work of reference. It does include, however, some very interesting keys for the identification of members of the various groups and might be of assistance to field workers who had had a thorough basic training in zoology.

Macmillan Company, 1923.

Economics of the Household; Its Administration and Finance

This book by Benjamin R. Andrews seems to be designed primarily as text dealing with the household management problems and a consideration of the economic matters affecting it. The matters of income, expenditures, capital and savings, insurance, housing, food, clothing and other items are primary considerations in the adjustments of the economic plan to desires and ambitions. Whether the budget, expenditures and classifications are possible in the average home is a question, but even the most careless learn the advisability of planned expenditures over a period of time.

The Macmillan Company, New York, 1923.

Health Training in Schools

With the increasing emphasis upon this subject, this hand book by Theresa Dunsdil for teachers and health workers is invaluable. It is offered apparently as an inclusive course of study in practical hygiene for state and local school systems, to assist in the inculcation of actual health habits. The stories, examples and games introduced make the book an indispensable assistant. The outline is graded and constructed with reference to material included to facilitate and emphasize the points to be brought out for each group available from a wealth of experience and work.

National Tuberculosis Assn., New York, 1923.

The Family and Its Members

The author, Anna Garlin Spencer, has included in her text many of the moot points of social and family life. Material is presented carefully and thoughtfully, questions for review are attached to each chapter and a bibliography adds to its general value. The family as a social institution, its various immediate and more remote members are discussed in their different relationships. The standards, the means for enforcing standards and needs are all developed. It should make an excellent basis for the study and consideration of all deeply concerned with the adjustments and change of family life.

Lippincott, Philadelphia, 1923.

Body and Soul

A study of faith healing, by Percy Dearmer, with an inquiry into the effect of religion upon health consisting of the citation and discussion of cases presumably healed.

E. P. Dutton and Company, New York, 1909.

The Infant and Young Child

As a manual concerning the care and feeding of children from birth until school age, the present book by Morse, Wyman and Hill, fills a very real place. Bathing, feeding, growth and development, care and training, diseases and the thousand questions arising are all translated into readable, usable form. It is interesting to note that the authors state that a child two weeks of age may be placed outdoors with some precautions. This happens to be one of the features not usually emphasized in books of the type and yet one of the most necessary instructions for proper care.

W. B. Landers and Company, Philadelphia, 1923.

No Need to Stammer

The correction or treatment of stammering seems to be twofold, according to H. St. John Rumsey: psychical methods which correct the underlying emotional side and physical methods inculcating a right method of breathing and to correct, coordinate and re-educate the mechanisms involved in speech. The present book is simple, readable and suggestive of methods to overcome the imperfect use of articulating or vocalizing mechanisms, or the faulty coordination, such as simple exercise, proper breathing, and a careful analysis of causes.

Dodd, Mead & Company, New York, 1923.

Smithsonian Health Museum

The material being assembled for the Health Museum in the Smithsonian Institution in Washington includes gifts from various government departments, the American Red Cross, the Life Extension Institute and other agencies.

The monthly Digest of the National Health Council for September announces that the U. S. Women's Bureau has about completed an exhibit on industrial hygiene, the American Child Health Association is working on an exhibit on child hygiene, and the U. S. Public Health Service is to turn over the exhibits which have been returned from the exposition in Brazil. Surgeon General H. S. Cumming, chairman of the committee, is in charge of this health museum and Mr. James A. Tobey is secretary.

The Law and Disease Prevention

"A court decision important in the annals of health legislation" is the way the United States Public Health Service at Washington characterizes the recent ruling of the District Court of Appeals, Second District, Division 1, of California.

Marie Clemente, arrested and charged with conducting a disorderly house, petitioned the court for a writ of habeas corpus setting forth that she was being illegally detained and restrained of her liberty by the chief of police of the City of Los Angeles acting under instructions from the health department of that city not to release her until she had submitted to an examination ordered to be made by the health department for the purpose of determining whether she was affected with a contagious or infectious disease.

The District Court of Appeals held that information that a woman is not only conducting a house of ill-fame,

but also personally participating in the unlawful acts carried on therein furnishes reasonable ground to believe that she is affected with an infectious disease, authorizing the health department to enforce quarantine measures against her. The woman was remanded to the custody of the chief of police.

As far back as 1919 the United States Public Health Service, in a bulletin prepared by direction of the Surgeon General, V. D. Bulletin No. 39, advocated a model city ordinance which provided that all persons reasonably suspected of having a social disease in the infectious stage be examined by the health officer or under his direction. Whom might be considered a reasonable suspect in such cases has been a point of controversy in many localities. The recent decision in California, says the Public Health Service, helps to clear up this much debated question.

Heads New Bureau of Home Economics

Dr. Louise Stanley, a native of Nashville, and now dean of home economics at the University of Missouri, has been selected by Secretary Wallace to head the newly established Bureau of Home Economics of the U. S. Department of Agriculture. She assumed her duties September 1.

About fifty employees will be attached to the bureau Miss Stanley will administer, and about \$72,000 a year will be required to maintain its activities. She will receive a salary of about five thousand dollars a year.

To Rid the World of Leprosy

(Continued from page 801)

further work, looking to the elimination of leprosy from that continent.

The investigation so far conducted indicates that leprosy exists in all the countries of South America except Chile. Colombia seems to have a larger leper population than any other one of the South American countries, although the proportion is high in Venezuela, Ecuador, Brazil, Argentina, and Paraguay. The disease exists chiefly in those countries where there is a considerable negro population or population of mixed blood.

In the leper hospitals the majority of patients are colored people. The prevailing attitude is not one of deep-seated, widespread abhorrence of the disease. Indifference to the conditions and the permitting of lepers to go on the streets can only be corrected by an educational campaign. It seems that only when patients become a burden to relatives or so disfigured that they cause disgust are they reported to the authorities.

Of the ten Republics, only four—Venezuela, Colombia, Ecuador and Brazil—have laws which may be considered stringent regarding the segregation of lepers. These four maintain official leper hospitals; but even in these countries the laws, good enough in themselves, are not rigidly enforced. Our investigation, says Dr. Danner, emphasizes the fact that officials of most of the countries would welcome any scientific help or suggestions for combating the disease.

This leads to the natural question of methods of cooperation by which South America can join forces in nation-wide, then continent-wide policies for ridding the whole world of leprosy. It is obvious how necessary it will be to extend operations into every area of the world where lepers are found and bring about governmental cooperation in the segregation of all lepers that they may receive

proper care. And when that has been done the day will be near when the world will be rid of leprosy. The claim of the world's lepers upon our sympathies, the preventive duty to ourselves and our neighbors, can not go unheeded. The task is real; the need urgent; it is at hand; it must be met.

Governmental action will follow upon the right leadership. Segregation will come as an economic policy. Humane care and oversight will re-

treated—another invaluable feature of segregation, viz., the opportunity for treatment of the disease in its insipient stages.

It is a governmental duty to learn of every case of leprosy within a country, immediately segregate the unfortunate victim, surround him with care and consideration, and, in the case of parenthood, save the child. Thus we protect society, which means our own families.

It is one privilege of the Mission

to Lepers to provide for the intellectual welfare, the social happiness, and the spiritual development of such wards of Governments.

Need for employment of their time should not be overlooked. Not alone suffering, but idleness has been the leper's portion in the past. Shut out from every human occupation, their minds have been undeveloped while

their bodies wasted. Minds as well as bodies must be rebuilt. Work for those still able is a godsend.

Partly as a result of the activities of the Mission to Lepers, the Governments of many lands are taking new heed to the leper question. They are persuaded that segregation is the beginning of the solution of the leper problem.

One encouraging phase of this governmental interest is the adoption of methods advocated by the Mission to Lepers in regard to the class of house for lepers and the general arrangement and management of leper colonies and settlements. Another result is the education of the public upon the subject of leprosy to the point where it is now believed a forward advance is possible that will rid the world of leprosy.

Wyoming has passed an act (*Ch. 63, Laws 1923*) to promote the health of employees in coal mines by providing bath houses at coal mines and prescribing penalties for its violation.

One of the modern bath houses at the National Leprosarium, Dominican Republic.

sult. Thousands upon thousands of hopeless lives will be transformed. At least one festering sore in humanity will be healed, and the world will be rid of this foe to its health and happiness.

Saving the Untainted

What may be called the most important phase in the segregation of lepers is the isolation of children from their parents in the hope that they have escaped the taint and will develop into sound men and women. Leprosy is not hereditary, and of course everyone who comes into contact with a leper does not contract the disease. However, one of the most obvious ways by which leprosy may be propagated is association of leperous parents with their children. In providing means for their early separation, always with regard for the parent's feelings and willing consent, society receives its greatest protection.

Occasionally a child of lepers shows signs of the disease and is separately

Rural Health Problem

(Continued from page 787)

subjects relating to agriculture and home economics, and to encourage the application of the same." Our state law which establishes the cooperative work in counties defines it as "agriculture, home-making, and country life." Yet nearly everything that we do has a bearing on health matters. Everything that increases income and profits helps to meet the basic need of money with which to purchase necessities. Every saving of time and strength to the farm woman means a chance for health. Every broadening contact means broadening of vision and understanding. Every farm garden, followed by canning and storage, means better diet. Every boy and girl who does food club or garden club or canning club work gets a better understanding of some health matters. Yet all these things are but incidental in their health bearing.

You ask what we see ahead in these matters. We see light. We have learned one thing in our extension work. We must not do things for people. Our task is to focus the attention of farmers and home-makers on their problems; to help them plan for the solution of these problems; to place at their disposal any resources which may be in our possession. It must, however, always be the people

themselves who do the work.

By parallel reasoning, I feel that it must be the people themselves who solve their health problem, under the guidance of the expert. The communal matters of water supply and sewage disposal and control of nuisances should be met by community action, and because the community feels the need. The other matters of home construction and personal habit and hygiene can never be successfully legislated or policed into existence; they will come only when the rank and file of people want them. The problem is therefore in no small part to make people want them.

In summary then, the problem reduces itself to two major elements: (1) The inculcation of a general and compelling desire for improvement of health conditions. This is essentially a problem of education and suggestion, in which I believe the demonstration method of agricultural extension work may well be considered as a possibility by the health-education agencies. (2), Adequate income to make the necessary physical provisions for sanitation and reasonable comfort. This, too, is a problem of education and adaptation, and one to which we are giving our major effort as extension workers in agriculture and home economics.

Australian Maternity Bonus

THE All Australian Women's Conference on the Maternity Bonus was held in Melbourne, in March 1923, for the purpose of discussing the benefits and defects of the Maternity Bonus Act that was introduced in 1912. Several papers, contained in the May issue of *Health*, the monthly journal of the Commonwealth Department of Health, present varying opinions expressed at the conference.

Edith Barrett, honorary home secretary of the Victorian National Council of Women holds that the motherhood of Australia is not receiving the best value from the bonus. She says:

There is no doubt it was thought at first that it would only be claimed by those who were not well-to-do. It is, as a matter of fact, claimed now by practically all women who give birth to children, irrespective of their financial position. For the year ending June 30, 1922, the bonus was

paid in the Commonwealth to 138,140 women. The total expenditure, including administration, was 706,000 pounds, of which approximately 15,500 pounds was expended on administration.

When it (the bonus) was introduced it was supported by very varied arguments. Those who took it most seriously asserted that it would increase the birth rate, or at least arrest the decline; that it would diminish the maternal and infantile mortality, and render a difficult and dangerous period in woman's life safer, and thus conduce to the national welfare.

Other people, fairly numerous, took the view that money spent in this way would do none of these things; that, if it were desired to effect the results mentioned above, the money could be better spent in other ways by providing institutions to which women could apply for instruction and help. More than ten years have passed, and it is now possible to form some idea of the result.

Miss Barrett thinks that the bonus has failed to produce the desired re-

sults. In support of her stand she cites the fact that the birth rate has since the introduction of the bonus, steadily and seriously declined. In 1907 the rate was 26.8 per 1,000 population; in 1921 the rate was 24.9.

It is also claimed that there has been no substantial reduction in the puerperal death rate and that the reduction in infant mortality has been trivial; much less than the reduction in other countries during the same period. The number of women attended at childbirth by a doctor has doubled since the bonus went into effect.

The author claims that while medical attention has increased there has been no reduction in mortality commensurate with the annual expenditure, and recommends (1) that existing state maternity hospitals be subsidized and aid extended to existing private hospitals, and others established where necessary; all to have ante-natal and postnatal clinics, and externe midwifery. It is recommended that (2) maternity convalescent homes be established and subsidized, and (3) help obtained for mothers confined in their own homes. Financial aid should be available (4) for bush nursing, district nursing, baby health centers, and other child welfare work, and resident nurseries and crèches in certain cases; and (5) means of dealing with exceptional cases, too far away to benefit from these schemes.

Dr. Marie Brown, delegate to the conference from the School for Mothers Institute, the Women Graduates Association, and the University Womens Union of South Australia, recommended a plan much like the one just described, believing that more could be accomplished with the available funds if they were expended for supervised care of mothers, and that the saving effected would leave a sum of money free for direct financial aid in cases of real need. New points suggested by Dr. Brown included a plan for trained domestics to help women confined at home and aid for increased scientific research in matters relating to the health of infants and pregnant mothers.

Women should not need paying for bearing children. That is part of their natural function and what they should willingly do. It should be a pleasure and a glory.

The bonus is often called the recognition of motherhood. Motherhood needs no recognition—it shouts for itself—but it should be made a normal and natural function, and not a disease.

Mrs. MacCallum, president of the National Council of Women, New South Wales cited the findings of the Council Committee that investigated this question. These findings were:

(a) That the majority of mothers do not abuse the bonus, but on the contrary obtain better medical advice and nursing services than they otherwise could.

(b) That any saving affected by a discrimination in income is not calculated to make much appreciable difference economically, and that it is better that no class distinction be made.

(c) That the bonus scheme, which reaches every mother in the Commonwealth, should not be superseded by any scheme less universal in its application.

(d) That the wish of the majority of mothers to be in their own homes should be recognized and respected.

(e) That the bonus scheme should be amplified by provision of facilities for pre-natal and post-natal care throughout the Commonwealth.

Of the 690,700 pounds paid out in the Commonwealth for the year ending June, 1922, only twenty-nine thousand pounds was paid to people whose incomes exceeded three hundred pounds. It is estimated that the administrative cost of discrimination would amount to the sum thus saved. The social aspect of the case must also be considered and under the present arrangement no stigma is attached to the bonus. Moreover, those receiving the bonus who are really able to pay the expenses, do pay for it themselves by taxes used in part to cover the bonus paid to others. "It should also be remembered that this is the only attempt to tax the single, the childless, and those past the age of rearing families, for the benefit of those who are having children.

The advocated policy of paying the funds direct to hospitals rather than to mothers is opposed to on the grounds that freedom of choice of doctor is no longer possible.

Mrs. MacCallum maintained that the bonus had been a great blessing to mothers and that no satisfactory substitute for it can be suggested, but that it should be supplemented by other schemes.

Miss Heagney of the Clerks' Union, Victoria, stated that the purchasing power of the five pound bonus was reduced nearly to three pounds in 1920, and is now worth three pounds, nine shillings compared to its 1913 value. She believes that the maternity allowance should be retained and that provisions should be added for a public maternity service and the endowment of motherhood.

There seemed to be quite a general agreement at the conference that bet-

ter provisions for ante-natal and post-natal care are needed. There was a difference of opinion as to whether or not the cash maternity bonus of five pounds was money well invested.

Control of Goitre in Central Europe

The control of goitre by the addition of potassium iodide to the common salt on sale in affected regions has become an accepted procedure in Switzerland (*Schweizerische Medizinische Wochenschrift*, March 1, 1923, p. 245) and has been strongly advocated in Austria (*Mitteilungen des Volksgesundheitsamtes*, March 24, 1923, pp. 81 and 100.)

Insurance Companies Cooperate in Statistical Study

An important contribution to American vital statistics has been made by the publication last April of a report on the mortality experience of industrial policy holders 1916-1920, based on the joint experience of the Colonial, John Hancock, Metropolitan, and Prudential Insurance Companies, and the Life Insurance Company of Virginia. These companies in 1920 included in the active membership of their industrial departments 26,000,000 men, women and children, not far from one quarter of the entire population of the United States and Canada, so that the data are of unique value. They are analyzed by age and principal causes of death for the period 1916-1920 in essentially the same form used in the earlier reports on mortality of insured wage earners issued by the Metropolitan Life Insurance Company.

Alliance for Care of Mental Disorders

What is believed to be the first instance in England of an alliance between a general hospital and a special hospital for the care of mental disease is a scheme recently approved whereby the Middlesex Hospital has opened two new wards for men and women, respectively, for the treatment of functional disorders of the nervous system. The patients will be under the care of the medical staff and nurses of St. Luke's Hospital for Mental Disease. Both hospitals share funds, material, and experience and service of the staff as may be necessary.

The resources of the general hospital in the nature of special examinations, medical and surgical treat-

ment and the like are available for the patients. (*Brit. Med. Jour.*, July 7, 1923, 3262, p. 31.)

Exhaustive Study of Aromatic Arsenical Compounds

Fourneau, Navarro-Martin and Trefonal (*Ann. de l'Inst. Pasteur*, Vol. 37, p. 551) present the results of a very exhaustive study of the various derivatives of $C_6H_5AsOH_2$ from the standpoint of toxicity on the one hand and of power to destroy trypanosomes and spirochaetes on the other. The quantitative relationships resulting from the substitution of varying numbers of amino and hydroxyl radicles at various points in the molecule are presented in detail. For the treatment of trypanosome diseases $C_6H_5(NH_2)_4(OH)_2(AsO_2H_2)$ combines highest parasitocidal value with lowest toxicity while $C_6H_5(NHCOCH_3)_4(OH)_2(AsO_2H_2)$ when administered by mouth is said to prevent and cure syphilis.

Milk-Borne Gastroenteritis

Positive proof of a typical bovine paracoli infection conveyed by milk to man has been reported by Christensen and Grinstead. (*Hospitalistidende*, April 11 and 18, 1923). Claim is made that, with the possible exception of a case reported in the *Journal of Infectious Diseases* by Meyer in 1916, this is the first instance in which conclusive evidence of such conveyance of infection has been obtained.

An epidemic of gastroenteritis occurred in a large hospital. Thirty-nine of the staff and 56 of the patients became ill; all recovered. It seems that on October 9, 1922, a cow on the farm supplying milk to the hospital, was taken ill with an offensive diarrhea and a temperature of 40° C. The milk had been mixed with that of the other cows and on the morning of the 11th cases appeared at the hospital. One patient admitted on the 10th was among those infected, showing that the incubation period was very short, while those admitted on the morning of the 11th escaped. On the night of the 11th-12th the cow died and necropsy showed definite signs of septicemia.

There is in Denmark a disease of calves known as "paracoli bacillosis." Adult cattle are usually considered immune. (*Lancet*, July 7, 1920, p. 26).

Senate Bill 22 of Ohio, effective July 29, makes the state narcotic laws conform to the Federal statutes.

KOTEX

The Last Word—

Just what every woman wants—the last word in comfort and convenience—the final reply to a puzzling question of hygiene.

Kotex are soft, light, and comfortable, besides being perfectly sanitary. They are made by carefully trained young women in work-rooms which fulfill the most modern standards of sanitation. Thus users of Kotex are given the priceless assurance of utmost cleanliness.

These accessories to the discriminating woman's toilette are the most satisfactory solution of a problem in personal hygiene. They are fast superseding unsanitary makeshifts, and are making an increasingly important contribution to public health.

Kotex are far superior to ordinary pads made of birdseye or absorbent cotton, because Cellucotton, used exclusively in Kotex, is the most effective absorbent material known to science. Moreover, this material is unique in being easily disposed of. The directions for disposal are found in each box.

Sold Everywhere—Ask for Them by Name

Hetch Hetchy Water Supply of San Francisco

(Continued from page 767)

and transmission lines from Moccasin Creek to San Francisco. The aqueduct through the Sierra foothills will be a tunnel, similar to that in the Mountain Division. The San Joaquin Valley will be crossed by steel pressure pipes, extending forty-five miles from Oakdale portal to Tesla portal. To develop the ultimate capacity of four hundred million gallons per day, three pipes of about seven feet diameter will be required. The detailed

very probable that with no other additions, water shortage would occur before the entire Hetch Hetchy aqueduct can be completed. Increased consumption from sources already developed east of the Bay, is limited by the capacity of the Spring Valley Water Company's bay crossing pipe line, which closely parallels the route of the Hetch Hetchy Aqueduct in this division. Rather than permit the corporation to invest capital in adding

to the capacity of the existing pipe line, San Francisco chose to construct the Bay Crossing Division of the Hetch Hetchy aqueduct in advance of the intervening links. Accordingly, plans have been prepared for a five-foot steel pipe line twenty miles long, between Irvington and a point three miles west of Redwood City. The right of way is being purchased for an ultimate installation of three pipe lines, each six feet four inches in diameter. Across the marshes adjacent to Dumbarton strait the pipe will be laid on trestles, and across the shallow part of the bay on a steel bridge. The channel crossing will require submarine construction—probably two three-foot pipes for the first unit.

Pulgas tunnel will connect the westerly end of the Bay Crossing Division with Crystal Springs reservoir. The tunnel is 8,700 feet long, and 97.94 square feet in net area.

Pulgas Tunnel is being constructed by Grant Smith & Company under contract for an estimated price of \$683,050. It was begun in August, 1922. Excavation is now about 65 per cent completed, and concrete lining has been commenced.

Upon its completion, the aqueduct from Irvington to Crystal Springs reservoir will be rented to the Spring Valley Water Company, and so used to carry water from Alameda County into San Francisco, until such time as the connecting links with Hetch Hetchy are completed.

Several units of the system will be enlarged or added to as demand for

water and power increases. O'Shaughnessy Dam will be raised from 226 feet to 312 feet. Lake Eleanor Dam will be raised. Two more power units will be added to the Moccasin Creek plant and new plants will be installed, utilizing the fall of water from Hetch Hetchy and Lake Eleanor Reservoirs to the aqueduct intake. A second transmission line will be built to San Francisco, and parallel steel pipes will be laid across the valleys until the ultimate capacity of four hundred million gallons daily is reached.

Department Store Health and Recreation

The department store of Gimbel Brothers in New York City has a force of employes that varies during the year from 3,800 to 5,000. About 55 per cent of these are women. All female applicants are seen by the nurse at the time of employment though physical examinations for employees are not compulsory.

The medical department consists of a suite of three rooms; one being the office of Miss M. B. Squire, the head nurse. Near the medical department on the second floor is located the store nursery, where mothers may leave their children in charge of a nurse while doing their shopping.

On the top floor of the building the company maintains a cafeteria in charge of a graduate dietitian. Here the employees may purchase meals at cost or if they prefer they are allowed to bring their lunch and eat it in the dining room.

Three recreation rooms are also provided. A nurse directly in charge of this portion of the work directs the dancing and group singing. There is also a portion of the roof sheltered by awnings that is used for recreation and rest.

A weekly absentee list is supplied to the medical department. "Coordinators" in each department report those employees living alone and extended absences reported for any of these lead to investigation.

During the month of April, 1923, 1,072 visits were made to the medical department; 809 visits from women and 263 from men. Dressings and treatment totalled 1,024, compensation cases 55, and customers 25.

All activities are supported by the company. There are no group benefit organizations or clubs.

O'Shaughnessy Dam under construction.

plans for this section and for the Coast Range tunnel have not been definitely fixed, and the program of construction will be partly determined by the action of the municipalities around San Francisco Bay in the matter of forming a water district.

The Coast Range will be penetrated by pressure tunnels, 31.5 miles from Tesla Portal to Irvington Gate House, broken by a steel siphon crossing the canyon of Alameda Creek. The hydraulic grade rate of this tunnel will be less than the slope from Moccasin Creek to Oakdale Portal, the tunnel crossing section being made larger than in the Sierra Nevada.

As the present water supply system of San Francisco is being used to its full capacity as now developed, it is

Severe Case of Static Flat Foot

is the cause of inefficiency and much bodily suffering. As a physician you will be interested in learning more about a most successful mode of treatment now used by thousands of successful practitioners in the treatment of weak arch or flat-foot, Morton's Toe, Metatarsalgia, Hallux Valgus, bunion, painful heel, weak ankles and other conditions where mechanical treatment is indicated.

Dr Scholl's Corrective Foot Appliances

with proper foot-gear and corrective foot exercises usually bring quick relief in such cases. There is an appliance especially designed for each individual foot condition. These appliances are sold and scientifically fitted by leading shoe dealers and surgical instrument houses in every city.

Write us for name and address of dealer nearest you and for the new pamphlet, "Foot Weakness and Correction for the Physician," including a chart of corrective foot exercises as recommended by the Medical Department, U. S. A.

Physical Condition of Jewish Children

(Continued from page 770)

be obtained. However, as a slight basis of comparison are presented the results of the physical examination of a group of school children in Detroit, Mich.

Early in 1922, medical inspectors of the Department of Health, Detroit, completed the examination of 8,887 school children, who were found on previous examinations to be 15 per cent or more underweight. Among these subnormal children 6,662, or 74.9 per cent were found to have one physical defect or more. Defects appearing most frequently were enlarged or infected tonsils and defective teeth.

Now among the children examined in Poland, 79.2 per cent are made up by such defects as tuberculosis, rachitis deformities, and other serious diseases outside of enlarged or infected tonsils, which Polish physicians did not think important enough to report in the face of more serious ailments.

The findings with regard to the incidence of tubercular infection (latent stage) among the Jewish children in Poland, as presented as Table IV., are compared in Chart I with the incidence of latent tubercular infection, as revealed by the tuberculin skin reaction, among the children of the poorer classes in Vienna, before the

war. Vienna has long been known as a city with a very high tuberculosis rate. The percentages are taken from the Children's Clinic of the University of Vienna. (Prof. Pirquet.)

We see that in Vienna there is an increasing rate of infection with the increasing age of the child. This is what we should expect, for with increasing age the sphere of human contact widens for the child, thereby enhancing its chances for infection. Chart I shows for every age but one, a higher rate of infection among the children in Poland than that for Vienna children. The fall of the curve for Polish children at the age of five is surely due to the fact that only a small number of children (80) have been tested with tuberculin.

The question of tuberculosis among the Jews in Poland presented some unexpected phenomena. Thus upon the study of this question it became evident that while the disease incidence was very high among the Jews of Poland, yet the mortality rate from tuberculosis was lower than that among non-Jews. The object of this paper was to show that the waste of war was not merely on the battle field and upon the national treasury, but also on the most precious possession of the nation—the child.

A Fresh Air Camp for Children

(Continued from page 772)

marked increase in the average weight: Entrance: Weight, 49; Height-Weight Index, 84. Discharge: Weight, 54.9; Height-Weight Index 93.5.

The greatest individual gain was 9.25 pounds, the least gain 1.12 pounds.

Still more astonishing was the sharp rise in the hemoglobin index. The figures are quite illuminating: Entrance Hemoglobin, 64.6; discharge hemoglobin, 81.5.

It is the intention to follow these cases up during the winter months in order to determine whether the improvement will be transitory or permanent. With proper supervision and proper food there should be no retrogradation.

The camp was operated over a period of approximately six weeks, July 9 to August 25, 1923. The total budget amounted to \$2,304.97 apportioned as shown below. It must be borne in mind

that the initial outlay for permanent supplies and equipment should not be charged against operating costs because they can be used from year to year.

Investment in Equipment

Furniture	\$144.80
Lumber	19.40
Hardware	81.00
Household goods	468.40
Plumbing	80.40
Kodak	25.00
Total	\$869.30

Operating Costs

Groceries	\$512.49
Milk and bread	246.87
Laundry	34.50
Insurance	53.20
Fuel	38.50
Telephone	14.85
Drying	49.50
Salaries	396.00
Miscellaneous	90.15
Total	\$1,435.67

The actual per capita operating cost of the camp was therefore \$63.97, a very nominal amount considering the benefits derived. The cost can be still further reduced next year due to the fact that the same personnel can take charge of a larger number of children than were cared for this year.

Every person directly interested in the camp is highly elated with the outcome. It has served to add further stimulus to public sentiment already alive to the tuberculosis problem of the community. Plans are being enthusiastically pushed in anticipation of a camp in 1924 capable of accommodating at least fifty children.

Koelsch reports symptoms of illness identical with those of brass founders' ague, observed in workers at a hot copper rolling plant in which the rolls were directly water-cooled. These observations, taken together with isolated reports in the literature and animal experiments lead the author to the presumption that similar symptoms may occur as the result of inhalation of the vapor of all heavy metals. (*J. Indust. Hyg.*, July, 1923, v. 3, p. 87.)

Exercise by means of popular games a part of the camp routine.

“Current civilization”

*makes this dietary adjunct almost
universally applicable*

Pyorrhea, scalp troubles, degenerative disease—

Modern life is perhaps unfairly blamed for a large percentage of these troubles.

But physicians are largely agreed that the increasing prevalence of constipation is due chiefly to the concentrated, artificial modern diet.

Where proper exercise and dietary regulation prove ineffective, fresh yeast has a distinct place in modern practice—both because it assists normal intestinal activity *without* the disadvantages of most laxatives, and because its vitamin content is an actual nutritional advantage.

During the past six years, extensive experiments have been conducted on scores of individuals, under the strictest scientific con-

trol. It has been definitely established that fresh Fleischmann's Yeast stimulates peristalsis, at the same time softening the fecal masses; and that it acts as a bowel regulator, rather than as a purge.

Best results are obtained by eating one cake half an hour before a meal or the last thing at night—followed by a glass of water. If desired, the yeast may be first dissolved in water, milk or fruit juices.

A new authoritative book: written by a physician for physicians. This brochure discusses the manufacture, physiology, chemistry and therapy of yeast. A copy will be sent you free upon request. Please use coupon, addressing The Fleischmann Co., Dept. Y-25, 701 Washington Street, New York, N. Y.

Cardiac Clinic of the Michael Reese Dispensary

(Continued from page 774)

taught in the hospital. In this manner, diversion is furnished for children while resting at home between the period of their hospitalization and their return to school. Interest in reading and the use of the public library is also stimulated as well as the use of meccano sets for the boys who are mechanically inclined.

The problem of medical follow up or medical supervision applies to all patients under observation in the cardiac clinic whether known to other agencies or not. This involves constant follow up to see that all laboratory work recommended is completed, that the patients report to other clinics for consultations and recommendations as well as that they return regularly to their own cardiac department. In this medical follow up work, the school nurses have been cooperative in using their influence for the return of the school children and in supervising some of the more difficult children in their home and school activities. The use of the mental hygiene clinic, recently established in the Dispensary has likewise proved a valuable resource in the treatment of cardiac children who present behavior problems.

In this brief survey of the work of this department, it might be interesting to note a few figures which indicate the scope of the cardiac problem as it exists today in the Michael

Reese Dispensary. During the six month period from June, 1922 to January, 1923 there were under observation in the cardiac clinic, 90 adults and 72 children making a total of 162 patients. In relation to the type of service rendered these patients by the social worker they may be classified as follows:

	Social case	Clinical	
	work	follow up	Total
Children...	24	24	72
Adults...	41	26	90

These figures readily show how much remains for development in this field of work. What of the 33 per cent of all the children in the clinic whom the social worker and physician know only through their slight contact during the busy clinic hours? What of the 25 per cent of adults whose home and working conditions are unknown except as we learn them in the routine interview at the first visit?

This department is constantly working with the Association for the Relief and Prevention of Cardiac Disease in Chicago as well as with the cardiac section of the Illinois Conference of Hospital Social Workers. Through these organizations, we are attempting to study the common problems in the cardiac field and to work toward their solution through the development of more adequate resources for both medical and social treatment of patients suffering from cardiac disease.

through congested automobile traffic causes a far greater number of casualties every day than football does in several years.

"Not all boys should be allowed to play football, however. Naturally, those who already suffer with some physical handicap cannot be permitted to take part. By physically handicapped we mean not only those who are obviously crippled, but also those who suffer from organic trouble, such as disease of the heart or lung. Therefore, before allowing a boy to play football he should be given a complete examination by a physician in order to determine his physical condition.

"There are two classes of injuries which may happen to a boy in a football game. The first which is of fairly frequent occurrence is the ordinary 'knockout.' Usually such an injury is unimportant; most often it is caused by a blow in the pit of the stomach which temporarily 'knocks the wind out,' or by a sudden blow on the head. In a moment or two the boy is up, none the worse for the shock. The second class of injury, which is relatively infrequent considering the number of boys who play football, includes dislocated joints and broken bones. The most frequent dislocation is of the shoulder. This can readily be put back by a physician, and in a short time the boy is as good as ever. The bone most commonly broken is the collar bone, less frequently the arm or leg. These more severe injuries to the bones and joints are much less likely to happen to the boy who has been properly conditioned or 'trained' and coached for the game. One of the points learned through competent coaching is how to fall when so tackled that a fall is inevitable. Just as for the screen the 'movie queen' can drop in a most realistic faint without hurting herself, so on the football field the boy may be taught to fall in such a way that there is practically no danger of broken bones. One seldom sees such injuries to the members of the great university teams where competent trainers and coaches are in constant supervision."

Summing it all up, if a boy is in good physical condition, if he has been properly trained, and if the team is well coached, he should not only be permitted but he should be encouraged to play football. "The boy is father to the man, and he will be a better man and a better citizen for having played the game."

Football and Health

FOOTBALL as affecting the health of the American boy was discussed by Dr. Matthias Nicoll, Jr., State Commissioner of Health, in a recent radio address, broadcasted from the General Electric Company's Station, WGY, at Schenectady.

"Football," said Dr. Nicoll, "goes far toward putting into a boy those qualities which make for real American citizenship. The game requires the suppression of the individual's craving for personal glory and promotes team play, and in modern life team play is the essential most in demand.

No father or mother wants his or her boy to be a "sissy," and football is one

of the best preventives.

"For many years the game of American football has been looked upon as a sport extremely dangerous to those taking part in it. Unquestionably twenty years ago there was a considerable element of danger attached to the game, but as a result of modifications of the rules of play in recent years, the hazard is far less than formerly. We do not mean to imply that the game even as it is played today is entirely free from the risk of bodily injury, but under modern conditions one cannot play or work or even live without constantly facing danger of some kind. As a matter of fact crossing city streets

MOTHERS!

*this will
interest you*

WHEN Pasteur made his great discovery which brought about the Pasteurizing of milk, it was a tremendous scientific step toward greater purity. When Heath made his remarkable discovery of Heathizing Ice-Cream, food scientists acclaimed it as an equally momentous achievement.

HEATHIZATION is the newly discovered method of making ice-cream in an atmosphere of purity and cleanliness. In making Heathized ice-cream, the ordinary air is driven out of the freezers and replaced with a clean, pure and sterile atmosphere. The result is a more delicious tasting and better flavored ice-cream. The texture of the ice-cream made this way is richer, more creamy, more appetizing.

BUT, above all, Heathization is a sanitary precaution. It protects the purity of ice-cream. There is a manufacturer of Heathized Ice-Cream in your city, so look for this "Sign of Purity" when buying ice-cream. If your dealer hasn't it, ask him to get it for you, or write us for further information.

for the period of the statistics. Two of these regions are rather heavily polluted while the other is not and the rates of all three are about the same. Mr. Doman said, "At first glance, it seems surprising to note that the two pollution predominating areas have typhoid morbidity rates that do not differ materially from that of the Litchfield region in which pollution may be regarded as negligible. In none of the three regions just considered is there extensive direct contact, and assuming comparable effects from other sources and means of transmitting typhoid, it is only logical that the morbidity rates for the three regions should not differ materially because of varying amounts of pollution."

In the two other regions in which vacationing and pollution are co-existent there is considerable direct contact between human beings and bodies of water receiving tremendous

amounts of sewage pollution. These regions represent a combined population of about 475,000, the morbidity rate being 40.9 per 100,000 or 129.0 per cent of the state average or 212.0 per cent of the average for the three regions mentioned above.

Mr. Doman continued, "However significant the typhoid morbidity figures may appear, I do not think that we are justified at this time in making the definite statement that water-courses polluted by domestic sewage act as a means of transmitting an appreciable amount of typhoid in this state. Before reaching so definite a conclusion, it must be realized that a great many details, not herein mentioned, must be considered. However, it is quite possible and it seems reasonable to believe that where we have considerable direct contact between human beings and bodies of water receiving enormous amounts of domestic sewage, more or less typhoid may be contracted."

Judge a Medicinal Mineral Oil by its Viscosity

BAINBRIDGE says, [Women's Medical Journal], "Liquid Petrolatum [medicinal mineral oil] is the agent which by common consent is pronounced the most satisfactory in the treatment of chronic intestinal stasis. - - - Some products are too thin, and consequently give rise to "dribbling", which is not only extremely disagreeable, but defeats the purpose for which the oil is given.

The London Lancet states that "oil of too easy fluidity [low viscosity] frequently has a disturbing effects upon the digestion."

Stanolind Liquid Paraffin [Heavy] — Tasteless, Odorless, Colorless — is a new medicinal petroleum product. It is a mineral white oil of ideal viscosity for the treatment of intestinal stasis.

Stanolind Liquid Paraffin is rich and heavy-bodied, and has specific gravity of 0.891 to 0.895 at 15 degrees C [59 degrees F]. Its viscosity is 300-310 Saybolt at 37.7 degrees C [100 degrees F].

Judged by its viscosity, as well as by its specific gravity and its absolute purity, Stanolind Liquid Paraffin [Heavy] meets the most exacting requirements of the medical profession.

ILETIN INSULIN, LILLY

Increased in Potency • Reduced in Price • Released for Sale

IT IS with profound satisfaction that Eli Lilly and Company announce success in producing Iletin (Insulin, Lilly) in such large quantities of approved potency and purity as to make possible a substantial reduction in price.

COINCIDENT with this reduction comes the release of Iletin for general distribution to physicians, through the drug trade. Heretofore it has been very properly restricted to experimenters and investigators. Sufficient experience has now been acquired, and the results of the studies so widely published, that the removal of former restrictions is warranted.

STATEMENTS appearing in the public press, to the effect that Iletin is available in very limited amount and is very high in price, are erroneous. Eli Lilly and Company are in position to supply quantities adequate to any conceivable demand at the very favorable prices quoted below:

REDUCED PRICES ON ILETIN

Effective October 15th, 1923

U-10, 5 c. c. Ampoule Vial containing 10 units to the c. c. (50 Units).....	\$1.10
U-20, 5 c. c. Ampoule Vial containing 20 units to the c. c. (100 Units).....	\$2.00

The increase in the strength of the Unit together with the reduction in price per 5 c. c. package is equivalent to a *reduction* of one-half from the prices prevailing previously.

It is the avowed policy of Eli Lilly and Company to price Iletin as low as consistent with a perfect product, efficient distribution, and a moderate manufacturing profit. Believing that Iletin should reach the consumer at the lowest possible price the thoughtful co-operation of physicians and distributors is invited.

Sincerely,

PRESIDENT ELI LILLY AND COMPANY

Problem of the Delicate Child

(Continued from page 778)

child may have all the rarebit she wants." It makes so much less difference to an adult than a child how his diet is arranged that parents need definite information. They think of their children in terms of themselves, like the little boy who wanted to find a baby policeman, and said with flowing tears that he had looked into every perambulator on the avenue and there "wasn't a little policeman in one of them!" We shall have to give parents the facts. Men and women must realize that instinct is of no account in civilization.

Witness the Guernsey calf! The high state of milk production brought about in its mother is death to the calf if the two are left together. The

restraining hand of man must keep the offspring from killing itself by enjoying its own mother's luxuriant milk flow. Such is the price of "civilization."

With opportunities to indulge in all sorts of one-sided, ill-assorted diets, we must have intelligent use of our resources, if we are to eradicate malnutrition. This knowledge is so fundamental as to claim a place in our educational program. It behooves us now to study the best way to impart it and make it function so that we may decrease the number of delicate children to burden society, even while we are learning to apply the remedial methods which our present situation demands.

Drunken Motor Drivers

THE working of the new law in Denmark providing that the motorist once convicted of drunkenness while driving may have his license permanently withdrawn is reviewed in a current issue of *The Lancet*. Two degrees of alcohol poisoning are specified: "drunkenness" and "being under the influence of alcohol." The difficulty of police regulation of the two conditions between which there can be no hard and fast line required the formulation of certain standards and criteria, which were devised with the aid of the Danish Medico-Legal Council.

Recognizing that determination by clinical rather than laboratory tests will be necessary in practice, the following program was devised as a guide to the police surgeon:

(1) Observe the driver's appearance. Drowsiness, drooping eyelids, relaxed features, congestion of the face and conjunctivae, sweating, slobbering, disordered dress, and the like should be noticed.

(2) Observe his behavior. Noisiness, silly behavior, excitement, garrulity, restlessness, and other characteristics should be noticed.

(3) Is his sense of time and space natural? If it is, say "Yes," if not, repeat his statements.

(4) Test his memory. Note if he can remember a couple of addresses, and test his ability to describe something, i. e., how the motor accident happened, or the meaning of a drawing in an illustrated paper.

(5) Note his speech; is it thick, nasal, lisping, or stammering? Let him repeat difficult words or read aloud a short notice in the paper.

(6) Note his gait. Swaying and ataxia should be noticed, and Romberg's test should be carried out.

(7) Test the movements of his hands and also his handwriting, telling him to write his name, age, station in life, and address on a sheet of paper.

(8) Note if his pulse is regular and rapid, the condition of his pupils, and his response to painful stimuli.

(9) Note if he smells of alcohol.

(10) Are there signs of other diseases such as epilepsy or apoplexy.

Dr. J. Fog of the Danish Medico-Legal Council was charged with the task of putting this scheme into practice, and he has already examined fifty alleged cases of alcohol poisoning in motor drivers. The account he gives of these examinations shows what an elaborate process the Medico-Legal Council has devised. The average duration of a single examination is about forty-five minutes. The medical examiner loses no time lest the condition in which he finds the driver should have changed since his arrest. The interview between the driver and the medical examiner is, as a rule, conducted in the absence of a third person, and the examiner hastens to assure the driver that he, the examiner, is a neutral, unbiased party, anxious only to find out the truth. In the quiet atmosphere of

this tête-à-tête meeting, the driver, whose excitement is solely due to an accident and the events following it, soon settles down and carries out the various tests satisfactorily. On the other hand, the drunken driver who has been temporarily sobered by the shock of an accident and the prospect of losing his license for ever, may at first pull himself together to pass certain tests. But the maintenance of such artificial sobriety for the better part of an hour is an almost impossible task, and if he is really drunk, the driver sooner or later betrays himself.

With regard to the value of the tests devised by the Medico-Legal Council, Dr. Fog has found that the fourth test is very delicate; none of the drivers classified as drunk, and hardly any classified as suffering from slight alcohol poisoning, could pass this test satisfactorily. But the fifth test, which also included sums in arithmetic, was of less value. Two drivers, who were found to be sober, could not pass simple arithmetical tests. Handwriting tests proved of little value, for the handwriting of comparatively uneducated men may be bad, however sober they may be. As for pulse-rate, it was of practically no value. Indeed, the average pulse-rate of the drivers discharged as sober was a little higher than that of the drivers declared drunk or suffering from slight alcohol poisoning. Test nine was of value only when negative; merely to smell of alcohol is of little diagnostic value. All the three drivers not smelling of alcohol were discharged as sober.

Dr. Fog's classification of his fifty cases brings out some interesting points. All the drivers were men, and the age of forty-one of them was between twenty and thirty-nine. There were thirty-four professional chauffeurs, and sixteen amateur or private drivers. In as many as thirty-four cases an examination was required between eight p. m. and eight a. m., and in nineteen of these cases an examination was required between midnight and six a. m. Only nine of the fifty drivers were discharged as sober. Of the remainder, eleven were classified as drunk, and thirty as suffering from slight alcohol poisoning. It is evident from this interesting paper that, under conditions obtaining in Denmark, the medical examination of a motor driver accused of drunkenness is so elaborate and systematically carried out as a matter of routine that there is little chance of a miscarriage of justice.

Clothing and Health

(Continued from page 783)

scribed by Dr. Rosenau in "Preventive Medicine and Hygiene," 1913 edition, direct quotations being introduced at frequent intervals. Pflügge put various subjects in ordinary pneumatic cabinets which were tightly closed, and timed them to see how long it took to produce signs of distress from fouling the air. The cabinet was then opened, filled with fresh air and the subject put back, but this time with his head protruding so that the lungs were filled with fresh air, and again timed for production of signs of distress. Much to Pflügge's surprise after a somewhat longer time, the subject began to gasp for breath, and to complain of dizziness and a sense of oppression. Just as soon as the water vapors in the chamber had reached a certain density, and the air a certain degree of heat, the signs of skin suffocation began to appear. Children and those with weak hearts showed such symptoms earlier than did more robust adults. If either the humidity or the temperature were lowered, relief was felt almost immediately. If both factors remained the same, and a current of air were passed through the cabinet, the patients were relieved. By giving a constant change of air to the body, it was prevented from surrounding itself with a moist, warm jacket of foul air. It is therefore exceedingly important that the clothing hang loose, or be of fabrics of open texture at all times. Undue radiation of heat as in winter, may be prevented by the use of several layers of suitable fabrics.

When infants and young children die in great numbers during an excessively warm summer, the quality of the food is usually called in question. In most of the studies of such conditions, however, there were found a high percentage who died of trouble unconnected with the gastro-intestinal tract but directly with the central nervous system. Heat strokes are not uncommon among infants and young children who have not been exposed to the direct rays of sun at all, "but kept in unventilated rooms, dressed in warm clothing, and often in rubber diapers," as Helmholtz re-

ports. Lack of ventilation is directly connected with infant mortality in a way that leaves no doubt, as to the importance of the free circulation of air over the whole surface of the body.

It is a well known fact that clothing tends to prevent radiation of heat from the body. In 1922 Talbert found that a thermometer inserted between the clothing and the body of an adult

lower, but actually lose weight unless water is taken very copiously. Stellwagon says that much of the skin trouble, such as prickly heat, boils, and the like, to which children are subject, are due in large measure to their being "too much clad." The remedy is removal of a large part of the clothing. In summer at the Johns Hopkins Hospital even the most

delicate children never wear more than a shirt and dress, in addition to the diaper.

In "Science of Nutrition," Prof. Graham Lusk says, "the most important constituent of clothing is air." Rübner has shown that the fur of such animals as the rabbit, skunk, and the like are most efficient in prevention of heat radiation. The whole of the fur consists of about 97 per cent air and 2 to 3 per cent of hair. This would therefore mean that all clothing should be so planned that the fabric contain a maximum amount of air spaces. That does not mean that body heat is quickly radiated. Quite the contrary is true. Count Rumford in Bavaria in the eighteenth century collected some experimental data which tended to prove that openness of texture is very much more significant in preventing radiation and conduction of heat from the body than the kind of fiber used.

The truth of the conclusions have been corroborated by investigators in England, and amplified by work done by Haven in Boston and McGowan and Sale in Washington.

It is a pretty well established fact that comfortable, healthy workers produce the best results in every walk of life. The converse of this is even more true. Unpleasant painful emotions from whatever source produce toxic influences which in turn lower working capacity accordingly. Comfort, physiologically and psychologically, underlies efficiency in a way which can be measured in dollars and cents. The truth of these conclusions has been demonstrated in the Yerkes laboratory at Harvard. Dr. George Ven Ness Dearborn, has reasons for believing that a "comfortable" person is more energetic, has more initiative, produces better work than when he is uncomfortable or unhappy.

registered from $\frac{1}{2}$ to 1 degree higher than on the same part of the body when unclothed. The same is probably as true of infants.

Sutton found that the metabolism of infants is increased by heat just as is the case in any other simple chemical reaction. This raises the temperature and thus a vicious circle is established. Rabbits were exposed to incubator temperature for twelve hours. Upon examination it was found that not only was the number of bacteria in the intestines increased, but *B. coli* were found in the liver and spleen. V. Salle found that exposure of 85 degrees F. not only decreased the amount of gastric secretion but their acidity and digestive activity with a corresponding loss of antiseptic and antifermentative action.

Meyer has shown that children not only do not grow as rapidly in hot weather as when the temperature is

Sterilize everything in one simple unit

INSTRUMENTS, dressings and water—all are positively sterilized in the Castle No. 1512. It is compact, convenient and avoids make-shift paraphernalia. Furthermore it makes your nurses and doctors sure of their sterilization.

The famous Rochester Sterilizer steams (dry) the dressings at 212°. Instruments are boiled in the lower section. Every drop of water in the urn is sterilized, gauge glass included. Any heat. Send for more details of the Sterilizer that you will want.

"Freedom from discomfort underlies it all." The higher grade of work being attempted, the more injurious or harmful will be the results of physical discomfort. "Comfort, in general is indispensable to ideal behavior that is at all free."

So it would follow that every painful corn, bunion, too tight sleeve, or unventilated undergarment costs you money other than that you pay the doctor. Besides lowering your earning capacity, uncomfortable feelings produce definite physical disturbances of normal activities. Even the recall of an "unhappiness" was sufficient to raise the blood pressure of a young woman school teacher, as shown in the chart, from "Psychology of Clothing," G. V. N. Dearborn.

The pulse beat is shown in the space between the upper and lower lines. If the recall of the feelings, while wearing an unbecoming, inappropriate dress, will increase the blood pressure, how much more acute must have been the reaction when the garment was giving the lady trouble. Similar records have been made of the reflex actions caused by various sorts of discomforts such as small objects in the shoes of marching soldiers. The disagreeable results are always accompanied by an increased rate of metabolism indicating a waste of energy, and a corresponding rise in the respiratory quotient.

The fine artists have been telling us this right along. Richard Wagner refused to wear any under garment not made of silk. He said the irritation caused by wearing rough fabrics disturbed his mind so that he

could not produce high grade compositions. The artists had a feeling for the truth, but have left the subject open for investigation of the scientific base facts, for the study of which Dr. Dearborn makes an appeal. He says:—"If 10 per cent be a moderate estimate of the present inefficiency arising from maladapted clothing, it is obvious that adequate endowment for the scientific study of human raiment is a public need—"

need not as yet widely realized, perhaps because never before scientifically defined."

Food Allergy as a Cause of Illness

The more interesting of the abdominal symptoms of food allergy as set forth by W. W. Duke, (*Journal A. M. A.*, Sept. 15, 1928), is abdominal pain, which may be either steady or griping, local or general, mild or severe, acute or chronic. It is often related to the eating of food, and frequently appears a few minutes after the ingestion of some particular food. Other alimentary symptoms of interest are dyspepsia, nausea, vomiting, bloating, diarrhea and mucous colitis, which may be either acute or chronic. Other general symptoms are the ocular, nasal, pharyngeal, bronchial and cutaneous. The neurologic symptoms are possibly worthy of especial mention. Weakness and nervousness are common. Other symptoms of interest are headache, arthritis, hypertension and bladder disorder. Arthritis is worthy of especial mention. Joint pain and swelling is a very definite and interesting manifestation of allergy. There is some similarity between the joint symptoms of acute articular rheumatism and that of a reaction of allergy.

Migration and rapid change, on the other hand, are striking characteristics of the symptoms due to allergy. Allergy should be suspected in any patient suffering from one or more of the symptoms mentioned, especially if there is past or family history of hay-fever, asthma, chronic urticaria, eczema or other symptoms characteristic of the condition. It should also be suspected in any patient displaying symptoms that cannot be accounted for by other clinical findings. The history is especially important if symptoms bear a relationship to the ingestion of certain foods. Dermal and intradermal tests are very useful aids in diagnosis. In food cases, however, skin tests, especially cutaneous tests, often fail completely. A diagnosis should not be considered proved unless symptoms can be relieved by withdrawal of the suspected food from the diet and reproduced again during a well period by the eating of the suspected food. As to treatment, the problem can be approached from four different angles: by (1) avoidance of the offending food; (2) specific protein treatment; (3) nonspecific protein treatment, and (4) symptomatic treatment. Avoidance is the method of choice when a patient is sensitive to a relatively uncommon article of diet. Specific protein treatment is justified only in the case of sensitiveness to foods used so commonly in cooking, as eggs, milk or wheat. Nonspecific protein treatment is justified in case one is unable to find and remove the substance causing the reaction. Symptomatic treatment with epinephrin and atropin is very useful in emergencies and for temporary relief.

Health Board Cannot Close Schools

According to an opinion recently rendered in Wisconsin, it is held that the state board of health cannot condemn and close school buildings, regardless of their condition. If on examination such buildings are found to be a menace and school authorities refuse to take action, the state board is powerless to close the school.

More Industrial Accidents

Statistics published by the Department of Labor in Industry, Harrisburg, Pa., indicate for the last six months a total of 100,421 industrial accidents, the highest post-war casualty record reported. A slight decrease in fatalities was reported as affecting June.

Specify and Insist on *Armour's* When Prescribing Thyroids

Since the advent of Thyroids as a medicinal agent all sorts of "active principles" have been exploited. Best results have been gotten, however, from Armour's Thyroids in powder and tablets.

The therapeutic value of Thyroids appears to lie in several things present in the gland which are preserved in the substance when carefully prepared.

In the manufacture of Armour's Thyroids the raw material is selected carefully. Fresh normal glands only are used. The finished product is standardized and runs 0.2% Iodine and contains the other elements of Thyroids uninjured by heat.

We supply Thyroid powder and 1/10, 1/4, 1/2, 1 and 2 grain tablets.

Each grain of Armour's Thyroid powder is equivalent to 5 grains of fresh glandular substance and each tablet contains the named amount of powdered Thyroids.

Pituitary Liquid, standardized, in ampoules. 1/2 c. c. obstetrical, 1 c. c. surgical.

Suprarenalin Solution 1:1000, water white, stable, free from preservatives.

Health Administrators Dilemma

(Continued from page 792)

accepted by American public opinion nor adopted as a governmental policy in any American state.

Furthermore, the countries where this concept of state medicine has become most clearly defined, boldly asserted and ably defended, have been Germany and England and in both the connecting link that has gradually operated to create the concept of the curative functions of medicine being an integral part of the state's public health machinery has been principally the adoption of the method of sickness treatment for certain low-paid groups in the industrial world together with partial cash compensation for time lost from gainful employment that is generally known as health insurance.

British Plan Applied

Taking the recent official utterances of the British Ministry of Health as a basis, German sources being lacking, it seems fair to conclude that Great Britain's sanitary authorities today consider the partial regulation of the field of general medical practice as an integral function of government. Again speaking very broadly and possibly far from accurately I am of the opinion that the attitude of American sanitary authorities, including Canadians, has been slowly but steadily swinging in the past few years away from this concept of state medicine as desirable or expedient for American conditions.

A resume of the propaganda for and against health insurance with the corresponding arguments that have gone on in the United States during the past few years, would be both interesting in itself and would definitely contribute to your clearer conception of this intricate question but would lead too far afield for the purposes of this evening—hence, I must ask you to be content with accepting the above statement without the evidence that should be brought forward to corroborate it.

Fortunately for us, we do not need to go into extensive analysis of the voluminous literature of the subject to obtain an authoritative statement as to what the sanitary spokesman of Great Britain today includes in the field of state medicine.

In his admirable memorandum recently published entitled, "An Outline of the Practice of Preventive

Medicine," Sir George Newman, chief medical officer of the Ministry of Health defines the objects of preventive medicine as follows:

(1) To develop and fortify the physique of the individual and thus to increase the capacity and powers of resistance of the individual and the community.

(2) To prevent or remove the causes and conditions of disease or of its propagation.

(3) To postpone the event of death and thus prolong the span of life.

To this terse and comprehensive statement of the objects of preventive medicine there will probably be no exceptions taken in any quarters.

He sums up the "principal elements" in an ordered sequence of a national policy in Preventive Medicine, as follows:

(1) Eugenics and the principles of sound breeding.

(2) Maternity and the care, protection and encouragement of motherhood.

(3) Infant welfare and the reduction of infant mortality.

(4) The health and physique of the school child and the adolescent.

(5) Sanitation and an improved personal and domestic environment.

(6) Industrial hygiene, the health of the worker in the work shop.

(7) The prevention and treatment of infectious diseases.

(8) The prevention and treatment of non-infectious diseases.

(9) The education of the people in hygiene.

(10) Scientific inquiry and investigation; and the extension of the boundaries of knowledge.

British State Health Code

A few quotations will show clearly just how much the "cure" concept is incorporated into the scheme of public health administration in Great Britain today. He says: "Above all an adequate medical service must seek to fulfill and conjoin all the varied elements of a national health policy environmental and personal. There must be no divorce between the epidemiologist and the practitioner."

Much of the latter part of Sir George Newman's "Outline" is devoted to a discussion of how the general medical practitioner can be made to feel the advantage of a closer correlation and at least a partial fusion of his field of activity with that of the official health service of the Nation. To quote again:—"In him (the general practitioner) should be realized the correlation of preventive and cur-

ative medicine. He should concern himself with measures for the maintenance of health as well as the curing of disease—." A few pages beyond he speaks of the more comprehensive scope of the new Ministry of Health when compared with the old Medical Department of the Local Government Board, its predecessor, and states distinctly "Not only is there the natural expansion of Preventive Medicine with the growth of knowledge and application but new duties of medical treatment must also be undertaken."

And to clinch definitely the concept of the present British Health Department of State Medicine embracing the curative practice of medicine, under the topic of medical organization he states that in each local unit of health administration there must be responsible health officers "and associated with these advisers and practitioners experienced in the various aspects of practical medicine, investigation (meaning presumably scientific research rather than ordinary inspection investigation) sanitation, tuberculosis, venereal disease, school medical work, general and insurance practice and so forth" and finally "For first preventive and curative medicine have to be brought together, and practiced in harmony. The extension of the public health service . . . means that every medical practitioner is a workman for the public health, a missionary of an imperial cause. He may seize the occasion with gladness or he may protest but he cannot escape."

These quotations have been made to show that there is good authority from highest official sources for the statement that the terms state medicine and preventive medicine are in common circulation in Great Britain today in almost, though not exactly a synonymous sense and that they definitely include the field of curative medicine as part and parcel of the jurisdiction of state health work.

There is something that fires the imagination and excites the sympathy of us all in this idealized figure of the old family doctor as the foremost exemplar and apostle of the latest tenets of hygiene, personal or public.

The difference of opinion comes in as to whether these ideals are being approached or left farther and farther

The Management of an Infant's Diet

Malnutrition, Marasmus, Infantile Atrophy, Athrepsia

Mellin's Food
Skimmed Milk (1% fat)
Water

8 level tablespoonfuls
9 fluidounces
15 fluidounces

This mixture contains 56.61 grams of carbohydrates, thus supplying material that is utilized rapidly for heat and energy. The predominating carbohydrate is MALTOSÉ, which has the highest point of assimilation of any of the sugars, is immediately available as fuel and may be safely given in comparatively large amounts. The daily intake of protein from the employment of this formula is 15.54 grams, an amount calculated to be sufficient to replace depleted tissues and to provide for new growth. There is present in the mixture 4.32 grams of salts for replenishing inorganic elements.

The suggested modification furnishes nutrition in keeping with the character and amount of food elements best adapted to the particular demands of infants in an extreme state of emaciation and serves well as a starting point in attempting to meet the nutritive requirements of these undernourished babies.

behind under the practical workings of the present British system.

Effectiveness of British Plan

Proponents and opponents alike of this system agree that the general practitioner is brought into a definite relationship with the health machinery of the nation principally by the practical workings of the Health Insurance Act. But while official and non-official advocates of the present British system point with pride to the operations of these recent laws as bringing more definitely into view the sanitary and hygienic millenium the opponents and critics view with alarm the practical workings of these same acts as being thoroughly ineffective from the standpoint of improving the public health, and definitely and directly pernicious in breaking down the independence of the medical profession and lowering the standards of competent medical practice.

And there we have it! Out of the welter of counter claims and cross accusations it is probably impossible to arrive at a fair, just, estimate of how the British experiment in state medicine is working out.

Arguments Against Insurance Act

Perhaps the most savage attack on the practical workings of the British Health Insurance Act is contained in a work by a British authority on legal medicine, Dr. William A. Brend, in his interesting volume "Health and the State." This work was published before the British Department of Health was created and is largely a piece of special pleading for the establishment of a National Department of Health, but it does not appear that there has been any material change in the relationship of the practitioner of medicine to the state brought about by the enactment of the National Ministry of Health Act. Dr. Brend's scathing arraignment of the shortcomings of the attempt to control curative medicine by government has been supplemented by many writers in the country; on the other hand the principles of health insurance have had very vigorous defense by able American sociologists, and to lesser degree by a few American physicians.

In order to give you some idea of the reverse of the picture portrayed by Sir George Newman, I will quote or summarize a few of Dr. Brend's most salient points:

(1) His first and fundamental criticism is that national insurance was lauded to the skies as a true public health measure and has failed to

produce results. He says "The National Insurance Act is the most ambitious piece of Public Health legislation ever carried through in this country. No previous measure has ever directly affected so large a number of persons, involved so great a cost, made such demands on administration, or been introduced with such lavish promises of benefit to follow; and no previous (public health) measure has ever failed so signally in its primary object."

(2) "The panel system has increased the element of commercialism in medical practice; it has done nothing to strengthen the interest of the doctor in the scientific side of his profession."

(3) That it was German in origin and had been in operation in that country for over twenty years prior to its introduction in England and had not produced public health results in that country.

(4) That it has not had any demonstrable effect in lowering maternal or infant mortality.

(5) That its cash benefits lead to excessive malingering but do not provide the deserving ill with the accessory special medical or surgical service, institutional or nursing care or convalescence facilities which are essential for earliest possible full restoration to health.

(6) That one of the most stressed points as to the public health value of health insurance, *i. e.*, that it would prove to be an indirect means to co-erce capital to improve insanitary surroundings which operated in shop or home against the physique of the working class, has never materialized in practice.

His many other objections he simply touches upon as not being essential to the public health aspect of the law. So much for solution number one, more government in private practice, as set forth by friend and foe. Personally I feel more and more convinced that this is not the wise road for us, even granting that perhaps it is the best for England with her infinitely heavier economic burdens and her astonishing percentage of population chronically below the economic boundary line of self-support.

Equip for Preventive Medicine?

Now let us consider very briefly the other alternative. We have called this the solution of bringing principles of preventive medicine definitely into the routine of private medical practice. It may well be called the practice of hygiene upon a "fee" rather than a "free" basis. Whether it ever

materializes or not is "up to" the American physician. I think I can see clearly everywhere evidences that the more progressive, more intelligent portion of our fellow citizens are every year, I almost said every day, becoming more and more ready for it.

But when they go to the physician with the idea of a "stitch in time" back of their minds—to unfold the trifling symptoms that are beginning to give them concern perhaps, or merely to have this bodily mechanism overhauled by their family biologic mechanic, what sort of a reception do they often get? You all know as well as I. There is no need to go into the painful details. Take just the one field of infant personal hygiene for instance. I have been astonished at the number of instances that have come to me of late, directly and indirectly, of the experiences of intelligent, sensible, well poised mothers who have taken literally the advice we health department folk have so liberally broadcasted in recent years—"Consult your family physician regularly for advice on baby's care while baby is well. Don't wait till he gets sick." They report a totally indifferent medical man who in many instances has even reprimanded them for seeking him, who seemed to have no ideas or advice on tap as to what they should do regarding diet, hours of rest, clothing, airing, bathing, or training of a well baby—or how to proceed to examine physically and appraise the state of development of a well baby despite the fact that the mother stood there eager for such simple but scientific advice and would consider such advice well worth paying good money for.

As Yet Untrained

The plain fact is, of course, that the physician has not been trained for this sort of work at all in the medical school or during his hospital training. He almost feels ashamed to take anybody's money (except a life insurance company's) unless he can in return show some point at which the human motor is skipping, or its carburetor fouled, or its ignition points "pitted" or its chassis sprung. In other words, his medical school has failed totally to acquaint him with the A B C's of either the preventive or social sides of medicine and when his clientele comes to him seeking guidance in these directions he is all at sea, and lets them drift away only too often into the hands of the cultists, sectarians, and charlatans.

A famous Medical Product and its name

UNTIL 1869 there was no such substance in materia medica as Petroleum Jelly. For all compounding, animal or vegetable greases were used. These became rancid or deteriorated otherwise and brought impurities in contact with the human tissues.

In 1869 Robert A. Chesebrough discovered a process of manufacturing Petroleum Jelly without the aid of chemicals or acids. This process not only removed all the impurities of the crude petroleum, but avoided the presence of highly irritating residues.

Chesebrough called his product "VASELINE" Petroleum Jelly and it was immediately recognized as a wonderful addition to medical science.

His product has now become an article of world-wide repute.

All these years "Vaseline" Petroleum Jelly has remained without an equal for quality and purity.

It is unnecessary to remind those of the medical profession who know this bit of history that to assure obtaining the Chesebrough product the designation "Vaseline" should be used when prescribing petroleum jelly.

PETROLEUM JELLY

Every "Vaseline" Product is recommended everywhere because of its absolute purity and effectiveness.

GOOD HEALTH Is Largely a Matter of an Enlightened Public

Making a man healthy is primarily making him understand Nature's laws and how easy it is to follow them. People don't intentionally expose themselves to disease when they know how to avoid it. They don't allow flies free access to their food when they know the dangers of this practice.

There is no means of promoting health any more powerful than the use of moving pictures. They entertain as they instruct. The eye readily grasps the truth told in picture when the ear would lose much of the same truth told in words.

Many hospitals, sanitariums, public health officers, etc. are applying this means of entertainment and instruction with marked success. A great deal of film is now available which is ideally adapted to such work. And with a portable projector like the Acme, guaranteeing pictures of theatrical standard, you can get the maximum use out of a film. The Acme exclusive gold glass shutter is another big advantage since it enables you to stop anywhere on a film and show a still picture with no danger whatever.

Our long experience in the application of moving pictures to many uses might be of value to you in considering your particular problem. We will gladly put this experience at your service if you will use the attached coupon.

MacKenzie Classifies Disease

There has recently been published a very remarkable little book which emphasizes this same idea from a little different angle called "The Future of Medicine", by one of the greatest living masters of clinical medicine, Sir James MacKenzie. I wish time permitted the quotation at length of some of the more striking passages in it, where this same idea is emphasized. He outlines his whole theme, however, in the first few opening paragraphs by giving a classification of disease that is so simple and obvious that it is astonishing that a similar classification never seems to have been made before.

He pictures any or all disease processes as falling into four distinct stages.

(1) *The Predisposing Stage.* The stage in which the individual is as yet free from the actual disease but liable to be attacked either from some inherent weakness or from some outside source.

(2) *The (true) Early Stage.* When the disease has entered the system but has not produced as yet any perceptible alteration of tissue and the signs the disease produces are mainly subjective or symptomatic and states that *this* is the curable stage.

(3) *The Advanced Stage.* Destruction or modification of tissue and its presence revealed by physical signs.

(4) *The Final Stage.* When the patient is dead and post mortem study is in order.

He goes on to point out that in reality clinical medicine hitherto has only concerned itself with the third and fourth states, and is now confronted with the problem of understanding the first and second stages—and concludes by stating that the chief end in medicine to which all endeavors should be bent is the prevention and (actual) cure of disease, but that up to now this objective has not been clearly recognized by medical men, for the greatest efforts of the profession have been diverted to the more urgent calls for the relief of suffering and improvement of already impaired health. And then he points out graphically how impossible it is by the present "instruments of precision, complexity of procedure, mul-

tiplication of specialists" route to ever get to the real objective of medicine because the bulk of patients in the predisposing or early stages of disease are never seen by those who are systematically engaged in disease investigation.

Then he goes one step further and shows that to achieve the aim of medicine, i. e., prevention and cure in the curable stage, it is necessary to recognize disease in its inception and

demands of the hour, of reshaping their practice to cover the field of preventive therapeutics, and anticipatory diagnosis as outlined by MacKenzie or else facing the more than possibility of our profession seeing written above it the words in letters of fire:

Mene, mene, Tekel upharsin.

This is the problem we are facing—the problem of the true relationships and the best lines of develop-

ment of the respective functions at present, and in the future, of the health department and private practitioners of medicine. The health administrator is truly facing a dilemma for he cannot hope to satisfy either the almost fanatical demands of the health enthusiasts or the reactionary, stand-pat, backward-looking ideas of the conservative wing of the medical profession.

This is the problem I wish to present to you for your most careful consideration, and that not merely more the fleeting period of this evening's program, but for the months and years that must pass until this problem is definitely, and let us hope, fairly and wisely solved—the problem of the health department and the physician and what they are going to do to each other or for each other

in the next generation, and I believe this subject deserves much more careful study and much less half-baked vehement, often almost vituperative outbursts from both camps than has been the case for the past few years. For like all other fundamental social problems that directly affect daily life, it is far from one-sided, and upon its proper and statesmanlike solution there may well depend much of deepest concern, not merely to these two groups, but to the whole future prosperity and welfare of our nation.

Illinois Organizes Physical Examination Campaign

Sixteen organizations are represented in conferences preliminary to organization of a physical examination campaign in Illinois in accordance with the National Health Council plans. Dr. Isaac Rawlings is chairman of the preliminary organization committee.

Health the Universal Aim

Health is the indispensable foundation for the satisfaction of life. Everything of domestic joy or occupational success has to be built on bodily wholesomeness and vitality.

Health is essential to the enjoyment all through life of sports and active bodily exercise. It is also necessary to continuous capacity for hard work; and it is only through active play and hard work that anybody can make sure of the durable satisfactions of life.

To promote health in the individual, the family, and the community should be the constant aim of every good citizen in the American democracy.—Charles W. Eliot.

that the only individual who has opportunity for acquiring this knowledge is the general practitioner.

What the Health Administrator's Dilemma Really Is

To sum up; what the American health administrator's dilemma really is:

It is *not* what doctors think it is at all: i. e., of the health administrators being put on the defensive to justify their present procedures.

On the contrary, it is rather the problem of holding back this strong rising tide of popular sentiment for the "free treatment" idea, and of trying at the same time to make the general public understand that like all alleged panaceas this state medicine concept still has far from demonstrated that it can produce all the results claimed for it; while simultaneously waking up their professional brethren in private practice to the absolute necessity of rising to the

Increases Vitality

The Vit-O-Net Electrical Blanket by means of soothing magnetic heat eliminates the poisons from the pores and other waste channels.

Increases vitality—enabling one to conquer disease germs. With its aid the body absorbs magnetism—the pulsating life so vitally necessary to good health.

VIT-O-NET MAGNETIC BLANKET

is now used by scores of leading physicians and hospitals for treatment of Rheumatism, Bright's, Auto-Intoxication, Arthritis, Eclampsia, Pneumonia, etc.

A Safe Measure of Sanitation

THE health edict "Be Clean" carries a command to every builder, buyer, health worker, manufacturer in the land for, if cleanliness is necessary, it must be made possible in every situation where the lack of hygienic standard constitutes the fundamental health hazard.

If Vitrolite is used, a glance will tell the inspecting health officer whether a safe measure of sanitation is practised in school, cafeteria, or gymnasium; for Vitrolite gives early evidence of neglect in routine care, and corners of concealed accumulations do not exist as kindly harbors for deadly germs.

The dairyman, combating dirt as an industrial hazard, achieved the most outstanding modern object lesson in health when he turned live steam on his hermetically joined Vitrolite walls, thus forever fixing the sanitary requirements of his industry.

Antiquated installations are the bane of the sanitarian. Make sanitary installation attractive, and the incentive is provided to keep it clean. Make cleaning easy, and the trick of sanitary practice is turned.

The Vitrolite Company

VITROLITE
"Better Than Marble"

Dr. E. H. Marsh Succeeds Dr. Lakeman

Dr. Matthias Nicoll, Jr., New York state commissioner of health, announced recently the appointment of Dr. Edward H. Marsh of Brooklyn as secretary of the New York State Department of Health to succeed Curtis E. Lakeman who left the Department to take up work in New York City.

Dr. Marsh has been connected with the State Department of Health since 1917 at which time he was appointed sanitary supervisor. For a number of years he has served as Secretary of the Public Health Council and will continue to fill this position in connection with his new duties as secretary of the department. He will also have charge of the New York City branch office of the Department where he will continue to administer the post graduate courses of instruction for health officers and nurses which are conducted by the State Department of Health in cooperation with the University and Bellevue Hospital Medical College of New York University.

As Secretary of the State Department of Health he will exercise supervision over the educational and publication work of the department.

Labor Turnover and Accidents

From a study of the accident rate and turnover in four factories making different products, Kitson & Campbell found that during 1921 accidents occurred among all employees with a ratio of one to every four whereas they occurred among new employees with a ratio of one to each one hired.

The accompanying illustration shows the type of chart presented by the authors. It shows clearly the close relation between monthly deviations

from the average of new employees hired and the deviation from the average number of accidents among workers in a cutlery factory. The correspondence, though convincing, was not as close in curves presented for other factories.

The fluctuation in accidents followed to a slight degree the fluctuations in average working force but with a much closer correspondence the number of new employees.

It was estimated that if the number of new employees could be reduced to zero, the number of accidents would probably be reduced 75 per cent. It is also pointed out that in computing the cost of turnover from such items as spoiled work, damaged machinery, etc., a certain percentage of amounts paid in settlement for accidents should also be included.

An increased amount of time spent in instructing new workers might aid materially in reducing the number of industrial accidents. (*J. Indust. Hyg., July, 1923, v. 3, p. 92.*)

Bacteria in the Lungs

Stillman, on exposing mice to an atmosphere containing cultures of bacteria in the form of mist finds that the organisms readily penetrate into the lower respiratory tract.

Pneumococci usually disappear in a few hours and give rise to no infection. Hemolytic streptococci, however, remain for a considerable length of time and usually give rise to a general septicaemia. Attempts to determine the conditions under which pneumococci may reach the lung and cause infection were not successful.

The bacteria must penetrate to the smaller bronchi at least for they can be grown from very small portions removed from the periphery of the lung. (*Jour. Exp. Med., Aug. 1923, xxviii, 2, p. 117.*)

Routes of Infection in Cholera

In an exhaustive study of the fate of cholera vibrios in guinea pigs and rabbits Sanarelli (*Ann. de l'Inst. Pasteur, Vol. 37, p. 364*) shows that vibrios injected into the peritoneum pass by way of the blood stream to the intestines in a few minutes, that the bactericidal influence of the gastric juice in these animals is so great as to preclude direct transfer from mouth to intestine, and that vibrios placed on the mucous membranes of the mouth or nose or trachea may pass through the mucous epithelium and reach the intestines by way of the blood and lymph channels, though such passage is slow and irregular.

The Largest Chlorinator Installation Disinfects Sewage

Eighteen Vacuum Type Chlorinators with a combined capacity of six and one half tons of Chlorine a day recently completed at the Easterly Sewage Disposal Works of the City of Cleveland, Ohio

ONCE MORE Chlorinator records are shattered and a new "Largest Installation" comes to the fore. This plant disinfects the sewage of a large portion of the city of Cleveland. It is used to protect bathing beaches and illustrates the growing interest in sewage disinfection and the increasing attention that this problem is receiving.

To point out the value of Chlorine and W & T equipment in the treatment of sewage we have just issued our technical publication number 42 "Chlorine in Sewage Purification." We will be glad to mail you a copy on request.

IMPROVEMENT OF DIPHTHERIA ANTITOXIN

NOTWITHSTANDING the vast fund of experience and information which has been gained through the many years in which Diphtheria Antitoxin has become established in medical practice, our knowledge is nevertheless steadily increasing and improvements continue to be made in the method of manufacture.

In the early days of serum therapy the standardization of antitoxin was a haphazard proposition, and even the tests utilized for safeguarding its purity left much to be desired. All that is a thing of the past. The standardization of antitoxin is now a definite and accurately controlled procedure, so that its potency, as expressed in antitoxic units, is a certain guide to the physician in determining dosage. Thoroughly dependable tests for insuring the freedom of the product from bacterial contamination or toxic substances of whatever nature have also been developed.

During recent years research effort has largely been directed toward increasing the concentration of antitoxin—getting the therapeutic dose in a smaller bulk and eliminating unnecessary solid material, especially proteins. An antitoxin thus refined has obvious advantages. The smaller quantity is

easier for the physician to inject and less painful to the patient. Even more important, however, is the elimination of unnecessary albuminous substances which in certain patients may cause protein toxemia.

It is now possible, by methods of chemical precipitation, to so concentrate diphtheria antitoxin as to make a given volume many times as potent as the same amount of serum freshly separated from the blood of the treated horse. This is accomplished by precipitating the serum globulin, a constituent of the serum with which the antitoxic element is closely identified. Various methods of carrying out this concentration have been developed, the results of which vary—not only in the degree of the concentration, but also in the physical characteristics of the antitoxin thus obtained. It is very important that the concentration be effected without increasing the viscosity of the globulin to a degree sufficient to delay absorption when administered to the patient. Absorption is an important factor in the clinical response to antitoxin, whether the injections are given subcutaneously or intramuscularly; and delay in absorption is obviously a serious disadvantage.

The methods employed in the biological laboratory of Parke, Davis & Co. furnish a practical solution to this problem. The resultant antitoxin has a high concentration, a low content of protein in comparison with its unit strength, and on injection is absorbed with great rapidity.

To safeguard the potency of the product, every lot contains 40 per cent excess units at the date of issue—more than enough to insure the full labeled potency within the period of use for which it is dated.

Five sets of purity tests are carried out with every lot of antitoxin, to preclude the possibility of any contamination of the serum.

The development and rigid enforcement of these methods has given to the medical profession an antitoxin of high excellence, the purity and dependability of which are beyond all question.

Don't Let a Bad Germ Up!

Keep it down with

Semdac **Liquid Gloss**

(A SUPERIOR POLISH)

Says T. M. Prudden, M. D.: "Ordinary, well-ventilated rooms, are actually dust and bacteria repositories." The lightest stirring of activity or air, sends these bacteria-laden dust particles into the air, whence they may readily be taken into the system. In naturally ventilated rooms have been found over 2000 living bacteria in 10 litres of air!

Dust is harmless so long as it is prostrate. Semdac Liquid Gloss holds dust down—entangles it in a film of oil from which it cannot escape.

The more immaculate the hospital, the more appropriate is Semdac, for it makes cleanness visible in the bright freshness of a satin-surface polish.

Semdac Liquid Gloss cleans all finished surfaces of wood or metal, and floors. It does not gum or stick—because it is scientifically made in the laboratories of the Standard Oil Company (Indiana).

To Safeguard the Nose, Mouth and Throat Against Acute Infections

has been conclusively shown to be the main consideration in the prevention of the graver respiratory ills, such as pneumonia, bronchitis, sinus and middle ear disease, and so on, that make so many practitioners of medicine dread the advent of cold weather.

Immediate attention to the mildest cold or inflammation of the upper air passages, with routine cleansing of the mucous membrane, constitutes the most important detail in accomplishing the foregoing, and no antiseptic at the physician's command today assures naso-oral prophylaxis with such certainty and gratifying freedom from harmful or disagreeable effects as

Dioxogen

$H_2 O_2 12v$

Of course, Dioxogen, like any local measure, must be used thoroughly and made to reach every part of the naso-oral mucous membrane. But owing its action entirely to the large volume of pure oxygen it gives off when brought in contact with bacteria, and being absolutely free from toxic or irritating properties, it can be used as frequently and extensively as conditions may require.

Employed, therefore, according to the directions given herewith, and in conjunction with the systemic and supportive treatment dictated by the physician's judgment, every confidence can be placed in the ability of Dioxogen not only to control nose and throat infections, but also to prevent the development of the complications and sequelae that form their greatest menace.

The Dioxogen Treatment of Nose and Throat Colds

At the first sign of a nose and throat cold, the mucous surfaces should be swabbed thoroughly, though gently, with cotton pledges saturated with Dioxogen, diluted one part to three of warm water, especial care being used to reach back of the faucial pillars. If the condition indicates a severe infection, this swabbing by the medical attendant should be done twice a day. In addition to this, the patient should spray the nose and throat every hour or two with Dioxogen in a strength of four to six teaspoonfuls to a half glass of warm normal salt solution. The rapid control of the infection means grateful relief and the effectual prevention of complications and sequelae.

Change of Address

FOR the information and convenience of the profession we announce the removal of our American General Offices to our new building,

*9 and 11 East 41st Street
New York*

The new premises provide more extensive accommodations for the firm's American General Offices and adequately meet the growing requirements of the business. Special arrangements insure rapid communication between these offices and our New York Works and Laboratories.

A cordial invitation is extended to the profession to visit our new Exhibition Rooms at any convenient opportunity to inspect the display of Fine Chemicals, Galenicals, Medical and First-Aid Equipments for all climates, and other Products of the firm.

A New Standard

This modern 12 story structure, executed in beautifully toned light grey limestone, sets a new architectural standard for pure Gothic style office building. It is situated in the heart of New York's most exclusive business centre, opposite the Public Library, a prominent Fifth Avenue landmark.

The Bridgeport Department of Health Laboratory

*The Value of a Laboratory Is Directly Proportionate to Its Use by the
Community in the Control of Disease*

BY WILLIAM H. COON, M.D., HEALTH OFFICER, BRIDGEPORT, CONN.

WHEN, in 1918, the Bridgeport Department of Health was reorganized, enlarged and newly equipped to meet the needs of the community it serves, a fortunate combination of circumstances found the laboratory of the department housed in a new building designed for occupancy by the department of health and its various divisions.

Recognizing the important place the laboratory would occupy in the work of the department, considerable thought was given even from the time the architect's preliminary sketches were made to the proper layout of the laboratory and care taken to make adequate provision not only for its immediate needs but for the needs of the future.

The rooms to be used by the laboratory were planned with due regard for working convenience, the relation of the laboratory quarters to other divisions of the department, to natural lighting facilities and what not. When the rooms as laid out in the building plans were ready for occupancy they were fitted out with all necessary gas, water, and electrical fixtures, conveniently placed and with every accessory which would facilitate the laboratory's work.

When the Department of Health

moved into its new quarters it had then a laboratory conveniently placed on the third floor of the building, provided with all necessary equipment and utilities which would facilitate its work and with all necessary mechanical and scientific apparatus and materials.

Assignment of Space

The ten rooms, exclusive of the cold storage boxes, which are used for laboratory purposes, extend along either side of a central corridor, reached by two flights of stairs and by elevator service. The rooms in which light is a factor face north by east. The rooms on the other side of the building, and which are used in the mechanical work of the laboratory, face south by west. All rooms are exceedingly well lighted; the rooms on the north east frontage are separated from one another by partitions of glass and the partitions between the laboratory rooms and the corridor are of glass as well.

Altogether ten rooms are used for laboratory purposes. Three of these rooms have built-in sheet-steel hoods with exhaust duct extending upward through the ceiling, and one room has a large built-in hooded cabinet of glass for blood chemistry work and

other examinations which are attended with the production of annoying odors such as attend the analysis of garbage tankage and greases. One small room entered through the office of the director of the division is set aside for weighing on the analytical balance. The accompanying diagram shows the arrangement of the rooms used by the laboratory.

Refrigeration is provided by means of an automatic refrigerating machine placed in the basement of the building and controlled by an electrical thermostat in the main ice chest. The refrigerator is built into the laboratory and has compartments opening into the laboratory corridor and into the room used for the examination of milk samples. Altogether there are in the ice chest eight separate compartments each of approximately twenty-four cubic feet capacity, and one large box for general cold storage purposes with approximately 648 cubic feet capacity. The refrigerating machine used is rated at three and one-half tons capacity and with the thermostat set at 50 degrees F., provides a very efficient cooling apparatus, seldom needing attention other than the renewal of the ammonia tanks perhaps twice yearly, and the

View of general office showing closet for diphtheria cultures.

occasional filling of oil and grease cups.

Still another small room is set aside in which to house the animals used in the laboratory work. This room is provided with a concrete floor sloping from all sides towards the center that it may be easily flushed and kept clean and with an exhaust vent opening through the roof. In spite of these provisions and the most careful attention paid to the cleanliness of the room and animal cage, we have found it practically impossible to prevent the appearance of some odor from this source during the hot and moist days of summer months, although at other times no trouble is experienced. We will, however, be able to do away with what little annoyance appears by transferring the animals to summer quarters on the building roof. These quarters are now in process of construction.

Reference to the sketch giving the general arrangement of the rooms occupied by the laboratory will show five rooms on the northeasterly side of the building. These rooms were designed originally to receive the maximum amount of light compatible with strength of structure, and to secure proper lighting facilities for microscopic work. At the present time, however, all work with the microscope is carried on only with artificial light.

One, the corner room on this side is held in reserve for the future needs of the laboratory. The next room adjoining this and connected with a door is used for general chemical and analytical work. This room is provided with a built-in hood of glass and metal, with enclosed exhaust apparatus, and with a glass cabinet for

the storage of chemical supplies. This room receives light from windows which occupy the entire street frontage of the room and from the rooms on either side which are separated from it only by glass partitions which extend to the ceiling. Stout benches run along two sides of the room and these are provided with gas, water and electric fixtures conveniently placed.

The next room in order is occupied by the director of the laboratory for her personal office and as a quiet room for work with the microscope either by herself or her assistants. From this room opens another small room used in part as the laboratory library and

A view of general office and laboratory.

for work with the analytical balance which is kept there. The director's room opens into the rooms on either side and is separated from them by glass partitions.

The room on the right of the director's office is used as a general office, for office files and for the clerical work incidental to laboratory administration. Into one corner of this room is set a glass cabinet. This cabinet is provided with all facilities for the handling of diphtheria cultures and no cultures of diphtheria are handled elsewhere except in this room. After the cultures have been smeared and stained they are removed immediately to the autoclave in the general

utility room for sterilization.

On the other side of the corridor and facing the reserve room of the laboratory is a room used for general purposes. Here all glassware in use by the division is washed and stored. In the center of the room is a large soapstone sink provided with a hood and exhaust apparatus. Three sides of this sink have self-draining service shelves. This room is very well lighted by large windows occupying the greater part of the entire area of the two sides of the room facing south and west. Another sink placed by the wall is used for the supply and discharge of two large water stills. One side of the room is occupied by a cabinet for glass ware, two other sides are occupied by benches and tables for gas ovens and other apparatus, and by a large autoclave.

Next to the general utility room is a small room used for general storage purposes and for laboratory supplies of one kind and another.

Next in order to the storage on this side and facing into the corridor are four large ice boxes and beside them a door leading into the main ice box. This box has nine feet head room, is approximately five feet wide and is used for the cold storage of biological supplies and other materials. Other ice boxes, four in number, open into one of two rooms which are used in general for the milk work of the department and for Wassermann tests. The wall space of the outer of these two rooms is used for the chart records of milk examinations. The records of all milk analyses are, of course, carefully kept through a system of card cataloguing, but for purposes of convenience and immediate

Ice boxes opening into corridor.

Director's office and view of room devoted to clinical analyses.

View showing the efficient arrangement of wash and general utility room.

comparison they are also kept on large charts so arranged as to cover all records for any one group for a period of six months. One chart, for instance, covers the record of all dealers selling Grade A raw milk in Bridgeport. In the outer left hand column of the chart the names of all dealers are arranged alphabetically; the next few vertical columns give against the name of the dealer his average for fats, total solids, bacteria and cleanliness for the preceding six months. Then follows his record posted as soon as examinations of his supply are made, for each of the other months of the year. Similar charts are used for Pasteurized milk dealers and plants and for ice cream dealers and manufacturers. Another chart kept in this room has proved of material value in checking up the records of herds in which tuberculin tests have been or are to be made. The regulations under which Grade A Raw milk is permitted sale in Bridgeport requires the tuberculin testing at least once each year of all herds producing this grade of milk. A good sized chart, small enough nevertheless to be conveniently used has been arranged, which enables the laboratory and the Inspector of Milk to find out at a glance when any individual owner's test is due, and when the test has been made to record in a small space the results of the test.

The last room on this side of the corridor is used as an animal room. The guinea pigs, rabbits and small animals used by the laboratory are bred in hutches at one of the hospitals and three sheep contribute their supply of blood to the laboratory's requirements.

The laboratory maintains twelve

"culture stations" at various points about the city, so situated as to be conveniently accessible to physicians. Ten of these stations are placed in drug stores. One station is maintained in a building chiefly occupied by physicians and there is another open twenty-four hours of the day, at the city emergency hospital. Each of these stations is provided with a supply of containers for specimens of urine, slides for blood smears and for the examination of gonococci, with Widal and pneumonia outfits, bottles for sputum specimens, and with culture outfits for diphtheria. Each station is provided also with a self-regulating, electrically controlled incubator. Physicians who place their diphtheria cultures in the incubator in the evening receive a report on these cultures the following morning. Collections are made from each station by ten o'clock at the latest each morning. At some of the stations in which adequate facilities are provided supplies of biological products are kept for the convenience of physicians.

Laboratory Equipment

Perhaps it is as well to state here that each year the Board of Health Commissioner has requested from the Board of Apportionment of the city, funds sufficient to supply the laboratory with all necessary new equipment, with equipment replacement, and with all necessary supplies. There has been no time in which this request has not been allowed in full. No need of the laboratory has been left unfilled. The laboratory has, in short, all the facilities and equipment necessary to carry on the work it is now doing, and there seems to be no

question that funds for any laboratory purpose the use of which would be of benefit to the community, would fail to be appropriated if requested.

For water and food analyses the laboratory is provided with a Kjeedahl still for the determination of free and albuminoid ammonia, an analytical balance, an immersion refractometer, a DuBoscq colorimeter, a small muffle furnace for ash determination, water baths, and the many incidental pieces of minor apparatus necessary for the proper examination of these materials.

For bacteriological work there are three compound microscopes, an electrically controlled incubator, autoclave, dry oven and Arnold Sterilizers. The equipment for milk examinations includes a Babcock centrifuge and dipping refractometer. There is a microtome for mounting specimens for pathological specimens and many other pieces of apparatus necessary to the work usually carried on in the laboratory of a health department.

This work or rather the work of the division of laboratories of the Bridgeport Health Department may for purposes of description be grouped into

(1) *Bacteriological examinations* for the physicians of the city, for the city clinics and for city hospitals. These include examinations of specimens for diphtheria diagnosis and release, tuberculosis, gonorrhea, syphilis, typhoid fever, paratyphoid, cerebrospinal meningitis, pneumonia, malaria, ring worm, Vincent's angina and dysentery.

(2) *Pathological examinations.*—Specimens of tissue are prepared for micro—(Continued on page 913)

Weapons and Tactics Used in the Battle With Diphtheria

Demonstration is Better Than Propaganda in Health Effort. Here is the Method of Waging a Health War in Your Own Home Town

BY FREDERICK W. SEARS, M.D., DISTRICT STATE HEALTH OFFICER, SYRACUSE, N. Y.

DIPHtheria is a scourge of mankind for which there is but little excuse. It may be said that the diphtheria morbidity rate of the average American community is the fault of the public health officials in charge, but this would doubtless be unfair even though every public health officer is well aware of the ways and means for securing large reductions in the diphtheria morbidity and mortality rates, for efficient diphtheria control depends to so large an extent on the cooperation of the family physician and the parents or guardians. The well known reduction in the case mortality of this disease that has taken place during recent years is a credit to curative medicine. The timely use of antitoxin has been an immeasurable blessing to the race; the problem now facing the health administrator is one of education.

Present accomplishments are of sufficient quality and quantity to prove beyond doubt the value of actively immunizing all susceptible individuals against an attack of diphtheria. Demonstrations have convinced the health officer that such a course of action is highly effective and much to be desired. In this land of the free, most of us are willing to be led and but few of us willing to be driven to a new pasture though the grass be ever so much more succulent and the shade more inviting.

This condition holds, in fact, for the entire field of public health. Mankind gets few blessings that it does not desire. Here, then, is the problem;

educate the fathers and mothers of the land to ask the family physician to immunize all their children early in life by means of toxin-antitoxin and secure the promise of the family physician to give and even urge such treatment. Even though the public official may in time thus work himself out of a job it seems certain that few of this day and generation will be

In a community where toxin-antitoxin treatment is unknown, what then is the first move? The physicians of course know about Schick testing and immunization but there may be many who are inclined to consider it as a display card of the immunologist rather than as a regular procedure for the practitioner. Again, some may be indifferent. Hence the first and most

fundamental step is to convince all physicians of the simplicity and effectiveness of testing and immunization. Talks to groups are of value but it is also true that personal and informal conversations whenever the health officer meets the practitioner are by no means ineffective. Tell the physicians of your plans at every opportunity and when they have received the benefits of a good amount of propaganda turn the attack on the next group.

After testing out the attitude of the physicians and converting the indif-

ferent, thorough newspaper publicity is most effective in reaching the school teachers and parents. One method of insuring intelligent journalistic handling of this phase of the work is to Schick the reporter who handles this phase of the work and immunize his children. With this experience and a simple explanation of the basic scientific facts involved he is much more apt to produce material that will sound convincing to the public.

Under present conditions the greatest opportunity for securing results is in the schools. While the general newspaper publicity is in progress the teachers can be given more informa-

Schick testing and antitoxin treatment have proved the greatest possible boon to preventive medicine. Where epidemics have raged, subsequent immunity is gained at the cost of human life, but Schick testing universally employed is a life-saving measure.

crowned with such success in their efforts. Too many weeds still abound in the "untilled fields of public health."

Little can be accomplished against the forces of indifference and opposition by a frontal attack. Crush both these wings with educational publicity and science can drive diphtheria to the marshy fringes of the universe.

Method of Attack

As already stated, the past reduction in the diphtheria mortality rate is a credit to medical science. Equal, if not greater, glory and honor will belong to those who reduce the morbidity.

tion through regular channels. The school children are then given printed forms setting forth very briefly the purpose, benefits, and effects of the Schick test and immunization. At the bottom of this sheet should be a consent blank for the signature of the parent or guardian.

Now the benefit of the earlier part of the program of attack will become apparent. "Johnny" comes home with the consent slip and announces that the doctor is coming to their school in a little while to see how many of them may catch diphtheria and that he will fix those that may so that they can't. The teacher has told them what a wonderful thing this will be, and "Johnny" wants father to sign the slip. To father this is a new thing; he either asks somebody else or calls up the family doctor. If the doctor says it is a good thing father signs the slip. If the physician has not been approached in relation to the forthcoming program he may be indifferent. Father senses this immediately and soon all the neighbors know that the doctor doesn't think much about it. Under such conditions failure is almost certain.

If, however, the physicians, the press, the school authorities and the parents are shown the value of Schick testing and toxin-antitoxin treatment, success crowns the difficult part of the offensive. A good majority of the children return with signed consent slips. The actual work then remains, but it is only an administrative and routine procedure then to test the children in the schools, read the tests, and to those showing positive reactions administer at weekly intervals, three doses of toxin-antitoxin mixture.

The Ideal Method

Six months to a year later re-Schick and get your reward. Immunize children entering school thereafter and diphtheria cases in the schools will be few. The oldtime epidemic that riddled the schools every winter will be no more.

Such an attack on the diphtheria problem as is outlined above is of value under the present conditions.

It is not to be considered ideal, but with such a scheme in operation there is a support for further effort to the end that all children between the ages six months and five years (without a Schick test) be immunized by the family doctor. Such protection is due the child when it reaches the most susceptible age and ventures out into society.

Before this ideal is attained, good can be accomplished by paying attention to the preschool children in

actions and received toxin-antitoxin treatment. No case of diphtheria has since occurred in this institution. The physician in charge of this orphanage happened to be the school physician and, being much impressed with the work done at the orphanage, it was not long before consent slips were given to the children attending one school.

From this point on the work progressed rapidly, the majority of children being tested and immunized during the winter months of 1922. Since then the work has included the children entering school and has extended to some of the preschool children. This latter part of the work is being particularly emphasized at present.

More than five thousand children, or approximately 72 per cent of the school enrollment have been given the Schick test. Sixty-three per cent of the tested children gave a positive reaction and 82 per cent of the more than three thousand positive children were given toxin-antitoxin.

The accompanying chart shows the number of cases of diphtheria and the number of deaths from this disease among the immunized and the non-immunized children from the close of the first demonstration in the spring of 1922 up to the beginning of the present school year. Among the nonimmunized group there were 83 cases and 14 deaths. Among the immunized group there were only 7 cases and one death. The record among this latter group, however, is probably too inclusive. All cases diagnosed as diphtheria have been included so that there may be no charge of juggling statistics. Most of them were later shown to be Vincent's angina and the one fatal case was probably a septicemia.

To summarize the figures for Auburn:

School population.....	7,105
Schicked	5,067
Positive reaction	3,083
Negative reaction.....	1,937
Not read.....	47
Immunized	2,546

It was found that in those sections of the city where diphtheria had formerly been most prevalent, the per-

centage of positive reactions was low. This, however, is only another indication of missed epidemics, the immunity has been secured at the cost of human life. It was also found that there was little variation among the English speaking races. Though the foreign race stocks have a low number of non-immune children, a larger percentage of them respond to toxin-antitoxin treatment than is found to be the case among the English-speaking (English, Scotch, Irish, and American) children. The following figures for three schools show the type of variations.

School but 9% foreign...85% positive
School 100% Polish....26% positive
School 92% Italian.....36% positive

The writer is inclined to believe from such findings as these and similar ones that the variations in immunity are not entirely due to the environmental factors affecting the different nationalities in the sections in which they congregate, but that there is also a purely racial factor involved.

Of 260 preschool children immunized in Auburn 90.3 per cent gave negative Schick reactions at the end of six months. This emphasized the point already brought out; namely, to obtain the maximum results children should be immunized early in life without bothering to give them the Schick test.

Work in Syracuse

In Syracuse 7,358 children have been tested. Of this number 3,949 were positive and 3,121 were negative, which means that 54 per cent were positive. The total school population of the city is 20,544. Eighty-one per cent of the positives have received one or more immunization treatments and 69 per cent have received all three.

As shown in the following table for more or less rural districts surrounding Syracuse, there is a relation between the per cent of foreign speaking peoples and the per cent of positive reactors.

Town—	Per cent Foreign	Per cent Positive
Solvay	50.1	48.0
Eastwood	40.0	63.0
East Syracuse.....	30.0	58.0
Baldwinsville.....	30.0	68.0
Weedsport	4.0	91.0
Homer	0.5	93.0
Fayetteville.....	0.5	93.0

The financial argument is always of value in dealing with the public officials that expend the public moneys. For example: It was shown that before Schick testing and immunization was introduced into the public schools of Auburn, during one term 14,205 days were lost by diphtheria cases, contacts and carriers. These lost

days cost the city \$6,871.16. During the first term of the next year, following diphtheria prevention work, but 415 days were lost at an expense of \$200.86. In all schools for the entire school year of 1921-1922 the loss was 22,438 days and \$10,860. During the next year this was reduced to 1,189 days and \$575.47. Such figures as these insure the allotment of more funds for the continued attack on the forces of disease.

Until such time as the family physician shall as a matter of routine immunize without Schicking all children in the families of his patients preliminary Schick testing must be continued. It is not recommended that the family physician use the Schick test. This can be done later to ascertain the results of immunization. Constant reading of tests and abundant experience is needed if conflicting results are to be avoided. It is difficult for the private practitioner to acquire this in sufficient quantity, hence the public official is the logical man to carry on this part of the work.

In both Auburn and Syracuse mothers are now bringing in pre-school children to clinics for Schick testing.

Rules to Observe

In starting a demonstration in schools it is well not to immunize the teachers at that time because of the possibility of getting a protein reaction in adults. One such occurrence may spoil the entire program.

Above all, keep very accurate records.

These are some of the tactics that experience has shown to be of value. With them have been presented some of the results accomplished with them. Time may show more and better weapons but the present need is for soldiers who will wage the war in their own home town.

Determination of Carbon Monoxide in Blood and Air

An apparatus for determining the amount of carbon monoxid in blood and air by the pyro tannic acid method, and compact enough to be carried in the pocket, has been described by Sayers, Yant, and Jones (*U. S. Bureau of Mines, Serial No. 2486, June 1923*). Colorimetric methods depending on the use of standards prepared from blood, proving unsatisfactory, standards have been developed and prepared from pigments.

In operation a sample of blood is taken, diluted, placed in a tube similar to those containing the standards,

the contents of a capsule of tannic and pyrogalllic acid added, and after allowing time for reaction, compared with the standards. The percentage of CO Hb in the blood is read directly.

For the determination of CO in the air, air sample bottles must be added to the outfit. Blood from a person who has not been exposed to CO is exposed to the air thus collected and the amount of CO Hb in the blood determined as before. By means of a chart the percentage of CO in the air can be calculated easily from the percentage blood saturation.

Bronchial Asthma Due to Mice

Emanations from all sorts of animals have been known to cause attacks of bronchial asthma, but a report by Dr. William Lintz in the *New York Medical Journal and Medical Record* is the first example of mice having been found as causing typical attacks from bronchial asthma. For the past seven years the patient had suffered attacks of asthma which occurred four or five times a month, principally at night, but occasionally in the day time, and chiefly from December till March. All tests failed to find the source of the trouble in food, weather, or the emanations from horse, cat, or dog, the attention of the number of mousetraps scattered about the premises led the physician to discover that the place was infested by rats and mice.

Suspicion that the mice were causing the trouble was further confirmed by the complete disappearance of the attacks when the patient sojourned in a home near by, known to be vermin proof, and their reappearance as soon as the patient returned to her own bedroom. To exclude any psychic influence tests, without the knowledge of the patient, made by exposing her to the emanations of a mouse when she was free from asthma, induced typical asthmatic attacks associated with intense dermatitis.

An energetic campaign against rats and mice in the home effected a complete cure. Dr. Lintz makes the report to support his thesis that every case of bronchial asthma is a separate piece of research work, and the physician can hope to effect a cure only through a knowledge of the patient's environment.

The Security Benefit Association will erect a \$200,000 hospital at Topeka, Kansas. Schmidt, Garden and Martin, Chicago, are the architects.

Eating for Health in the Tropics of Central America

In the Tropics As Elsewhere, the Palatability of the Food Depends Upon the Intelligence and Ingenuity of the Cook. A Balanced Ration Is Necessary Here As in the Temperate Zone

By WILLIAM COLBY RUCKER, M.S., M.D., CHIEF QUARANTINE OFFICER, THE PANAMA CANAL.

TO the average dweller of the temperate zone, the word tropics conveys the mental picture of waving palms, thatched or tile roofs, an easy existence surrounded by an army of deft, soft-footed servants, and a dietary in which exotic fruits and vegetables abound. It is vaguely supposed to be a hot region but no thought is given to the difficulties of securing ice for refrigeration. The unceasing warfare which must be carried on against kitchen vermin does not enter the picture. Rarely is it considered that to maintain health in the tropics, it is necessary to make a complete readjustment to an environment in which housing, clothing, habits, customs, servants, and foods are entirely alien to those of the homeland. In no particular is this more trying or important than in its relation to the feeding of the household.

The housewife who comes out from home soon finds that if she is going to set a good table she must do her own marketing, and here are encountered the difficulties of a different language and the trials of strange fruits and vegetables, new species of fish, and weird cuts of meat which to not appear to have been carved from any known animal. If she is slothful or lacking in initiative, she will fall back on the tin can, smoked meats, sausage, crackers and cheese, and a few cold storage products secured at infrequent intervals from passing ships or she will permit her cook to serve a native menu in which grease, red beans, and rice, garlic, and stews dominate with terrible monotony. The result is pretty apt to be gastric disaster.

If on the other hand, she is a real home-maker, the kind of woman who can throw around a one-night camp the atmosphere of an ancestral home, she will study the local market, she will learn how to prepare and serve whatsoever fresh foods she can secure, she will invent new dishes, or, better still, she will learn how to cook the native dishes and will then adapt them to the American digestion and appetite. She will not insist on serving exactly the same dietary as is the

most tropical dishes are more highly seasoned than at home. If one is kept on a monotonous or lop-sided diet, health maintenance is exceedingly difficult. At first there is always the temptation to indulge too heavily in the new fruits and other carbohydrates. Rashness in this direction should be avoided, as should also hideboundness about things which are different from those at home. An excessive meat diet is just as dangerous, since it is apt to set up a putrefac-

tive process in the intestinal tract and produce toxemia and chronic ill health. Perhaps the wide spread and very harmful tropical habit of frequent purges has as its foundation badly balanced rations.

The place to begin the study of how to set a tropical table is the market and there the housewife is pretty apt to have some unpleasant surprises in store for her. Regrettably it must be confessed that most tropical markets are

not conducive to a good appetite. To be sure, they may be marvels of cleanliness, sanitation, and order as in Colon and Panama; they may contain a wealth of fruits, flowers, and vegetables as in San Jose, Costa Rica, but quite the reverse is more apt to be the case. Perhaps the market is just an open plaza abounding in flies, dogs, and pigs, and the stalls merely a few palm leaves or an old piece of sacking. It may be just a street where unkempt slatterns squat smoking beside a few open baskets which catch all the dust from passing ox-carts and saddle horses. Sometimes they are dark, filthy little cells before which hang festoons of offal and gobbets of

If one wishes to keep well in the tropics, it is wise to market for one's self. It is surprising how many wholesome foods may be secured by carefully studying the local markets. At the boat market of Panama, R.P., fish, fruits, and vegetables may be had.

mode in the particular Badger Junction from whence she came. In other words, she will cut her menu according to her market. Other things being equal, the adoption of this policy will carry her family through what might well be a disagreeable or even dangerous experience without deprivation or harm.

The Zest for Food

It should be borne in mind that the newcomer from a temperate climate has a preliminary stimulation of the appetite and digestive functions. This soon passes leaving the taste for food and the powers of assimilation below par. Perhaps this is the reason that

meat. The romance of the tropics is oft-times greatest at a distance and with a nasal clothespin. But let not our marketer despair, safe food—not necessarily fancy food—may be secured at the price of research, vigilance and brains.

Green Foods Scarce

One surprising thing is the paucity of vegetables at the sea-level. In the higher hinterland they are far more plentiful and, as in Guatemala City, where it is said that fresh green peas may be had every day in the year, or in Caracas where bananas and grapes abound, the choice of most of the fruits and vegetables of the temperate and tropical zones may be had. These are exceptions however and in many places the arrival of a shipment of "States lettuce," i.e., head lettuce, creates a furor of excitement and housewives vie with one another in securing a supply which will last up to a safe limit of spoilage. Lack of industry and the absence of certain soil ingredients may have something to do with the scarcity of fresh vegetables in some tropical ports, certainly the carefully tended and well fertilized Chinese gardens produce well in Panama, but probably destructive insects are the real reason.

To compensate for this, there is almost always a splendid fish supply. Beautiful corbina, brilliant red-snapper, papagaya and parrot fish, silvery Spanish pompano and amber-jack are among the larger varieties; while mackerel, spots, grunts and many kinds of pan-fish abound. If fresh, they make an ideal tropical food, but it should not be forgotten that corbina produces an acute skin eruption in susceptible persons. Baked, boiled, broiled, or fried fish, either served plain or with a sauce, are on the menu of almost every tropical luncheon or dinner. Newcomers should secure competent advice before buy-

ing fish since several varieties are poisonous at certain seasons.

Shell fish are plentiful, shrimps, prawns, crabs and lobsters, oysters, clams, mussels, and scallops being easily secured in season. They must be absolutely fresh and go into the water "kicking" and they must not stand long before serving, since even with the best available refrigeration, they undergo decomposition rapidly in the hot, humid air of the tropics. In this connection it may be pointed out that food poisoning is not infrequent in warm countries. It is apt to occur in groups when a large number of people have been fed at a public place which is not equipped to serve so many people at one time.

A typical tropical garden. The trees in the foreground are papaya. They are always planted in pairs, since they will not bear unless male and female trees are close enough for cross fertilization. At the left sugar cane is growing. The small bushes at the right are yams, while pole beans are growing behind them.

Shell fish may be incriminated but any other putrescible food may be guilty. Nevertheless it is a safe rule to regard with suspicion all tropical shellfish unless one knows positively that they are freshly taken from the water.

Rice enters into many shell fish dishes. In Jamaica, for example rice and prawns are concocted into a delightful luncheon dish. To prepare boil shrimp or prawns and peel them. Put in a pan with a little olive oil, chopped green pepper, pimento, one tomato, one onion, water and rice. Season highly and add a bay leaf. Simmer slowly until the rice is cooked. Serve with half limes. To prepared in this way is not fluffy. To

make fluffy rice, as for curry and rice, clean the rice, wash in cold water, drop into boiling salted water, cook (about twenty minutes) until every grain stands for itself. Drain thorough a colander, pouring fresh boiling water through it to remove the mucilaginous content. Rice may be colored and delicately flavored with Spanish saffron or annato (*achote*) seeds.

In South America, *arroz abunda* is a favorite fish and shellfish dish. To prepare it, take a large iron pot and put in it some diced bacon, onions, thyme, and a bay leaf. Cook and stir until the onions are well browned. Add a good sized piece of firm, rather coarse fish with enough water to cover it. Boil and remove the fish and

strain out all the other solid material. Then add to the stock remaining, beginning with the one which takes the longest to cook, every sort of shell fish obtainable, crabs, lobsters, shrimp, prawns, clams, mussels, oysters, scallops and remove them when cooked. Add Spanish saffron to the remaining liquor, boil rice in it and drain it. To serve put a foundation of rice into each soup plate and heap on top of it a piece of the fish and enough shell fish to make a flattened cone. Then squeeze half a lemon over the mass and pour over it a little of the stock. Garnish with pimento. This dish is a meal in itself and will delight even the most jaded epicurean appetite.

Meat Not Savory

With the exception of cold storage importations, meats are not usually as good in the tropics as at home. If not tainted they are quite as healthful as in the United States but the animals have not been as skillfully fattened, slaughtered, and hung in the tropics. Of beef there is always a plenty but it is often rather "wild" tasting and as a rule butchered according to other standards than American. For a roast, for example, one gets what is called "loma"—a Spanish word meaning loin—a solid,

boneless, fat-free, fragment which resembles no cut ever seen north of the Rio Grande. Dry salted jerked beef called *tusajo* is a part of the Latin-American dietary which may add a pleasant variety to the menu. To prepare it, the meat is cut into one inch

uniformly of good quality and are safe.

In many tropical countries venison is plentiful and good, frequently being the cheapest meat on the market. There are also certain other game meats which are excellent. In Panama, for example, *conejo pintado*

cept geese, are plentiful, in fact chicken with rice is served with almost as appalling regularity as are fish and rice, or rice and red beans. Apparently they are athletic birds built for speed and endurance. In many places they are to be purchased from native women who walk about the streets with a number of fowls hung from each arm. Stepping aside for a moment, it may be noted that in the larger tropical towns there are so many different hucksters crying their wares from doorway to doorway that they are sometimes a positive nuisance. Each vociferously describes the merits of his goods. One with a basket on his head and a sheet of lottery tickets in the hand which he is not reserving for conversational purposes, is selling eggs. There are hand barrows loaded with golden oranges or shaggy cocoanuts and propelled by barefooted natives. Push-carts with pies, pastries, and candies bump along. Brown-eyed women gracefully balance pyramids of fruits on the glossy, black heads. Chinamen with expansive bamboo hats trot along with trays of green vegetables suspended from shoulder yokes. It is all very colorful, very exotic, but absolutely diabolical when added to the noise of shod horses, groaning ox-carts, and chattering parrakeets in a narrow, cobbled street which was laid a century before human foot

A Costa Rican banana plantation.

cubes and braised. It is then beaten with a flat stone and afterwards slowly simmered with a little olive oil, water, green peppers, tomato and onion, all well spiced. It is not as indigestible as it sounds and it has a high caloric value. Beef enters into the myriad of stews which are called by various names from *sancocho* to *guisado* but are none the less stews. Veal unless imported in cold storage, is more difficult to obtain. Many Americans find veal shanks a pleasant relief from the monotonous beef stew.

Meats Not Inspected

Goat meat is fairly plentiful in some places but is not popular except with the native poor. In Curacao dried, salted sides of goat are staple articles of everyday diet, in the same way that dried codfish is in Jamaica. Mutton is usually not plentiful. At the sea coast, it generally comes from Australia. It must be well trimmed and thoroughly scrubbed in salt water before serving. Fresh pork is generally plentiful. An acquaintance with the habits of the tropical pig is apt to discourage one's fondness for pork but the imported American variety is apt to be clean and wholesome. In this connection it is just as well to remember that in the tropics of the western hemisphere there are few countries which maintain an efficient veterinary service. Meats from the United States are almost

(translated "spotted hare") a sort of a gigantic guineapig, is a great delicacy tasting like superfine suckling pig. Also iguana, a sort of mammoth lizard, is held in high repute as possessing all of the combined prandial virtues of chicken, veal, and

frogs' legs but nevertheless not particularly popular with Americans. Pecary or wild-hog is highly thought of and turtle is easily digested and has a delicate flavor but is not of high nutritive value.

As a rule poultry of all kinds, ex-

pressed Plymouth Rock.

In Cuba *arroz con pollo* (chicken and rice) has risen almost to the dignity of a national dish and well it may for when properly cooked it is as pleasing to the palate as it is to the eye.—(Continued on page 915)

Medical Inspection of Schools and Correction of Defects*

Health Promotion Used as a Means of Stimulating the Intellectual Performance of Millions of Children to Be Educated at Public Expense

BY C. V. AKIN, SURGEON, U. S. PUBLIC HEALTH SERVICE, HAGERSTOWN, MD.

IN DISCUSSING medical inspection of school children it is not the author's purpose to outline the theoretical ideal of performance. Quite enough has been written and said about what should be done for the welfare of children of school age and not nearly enough time has been spent in determining exactly what the average community can and will do for this fraction of the population.

In this phase of public health work, as in other branches of community endeavor, one continually meets with extremes. On one hand there is the progressive community with an intense consciousness of what ought to be done and plenty of money to do it with. At the other end of the scale one finds a collection of people who through ignorance, indifference, or financial inability, do nothing. It is hardly necessary to assert that the latter is by far the more commonly met with.

It should not be inferred from the directness of approach to the subject under discussion that public attention should be focused on the hygiene of school children as being of paramount importance; a separate and specialized section of child health work. Such is not the case. To the contrary, the necessity for such work is to a very great extent occasioned by ineffective or inadequate protection during antecedent periods of life. The task of the school hygienist assumes its present proportions because children are permitted to enter school in whatever physical state the sixth or seventh birthday finds them.

It would indeed be well for the public to recognize the basic fact that the mere act of becoming of school age is not accompanied by a mysterious physiological transition which serves to differentiate the school child

from one of more tender years. He has acquired a few permanent teeth perhaps, and has lost his flowing curls but otherwise is identically the same as when he ran at large, free from intellectual burdens, and exempt from sanitary curiosity. There is much to be criticized in a system which permits a child to be arbitrarily committed to school on reaching a certain milestone in life irrespective of his physical or mental status. Physical examination of thousands of school children, ranging in age from six to sixteen, proves beyond the possibility of a doubt that a significant proportion of this group is required to take this first big step in fitting itself for citizenship foredoomed to partial failure because of defects and deficiencies which interfere with normal physical and mental function.

For the purpose of establishing and identifying the field of school health work we may safely conclude that the defects embarrassing children of school age are those to be found among the pre-school group, with such modifications on the one hand as are the result of self-limitation or correction, or such exaggerations on the other as are the natural consequences of disease progress or neglect. The period of a child's life spent in school may well be utilized in overcoming the ill effects of earlier omissions but it must be considered primarily as a time of preparation for maturity. A proper school health program would not only insure children good bodily machinery but they would be taught how to run it in the most efficient manner possible.

For the imposing number of children in school who are waging an up-hill fight, medical inspection represents a boon of greatest value. If taken in connection with adequate follow-up supervision and the prompt provision of corrections for children of parents who cannot afford private professional attention, it stands as a community service of unusual merit.

School hygiene, no doubt, lacks the essential protective value of prenatal, infant, and pre-school work but the majority of children at the time of admission to school are still susceptible to the beneficial effects of corrective measures. As a means of stimulating the intellectual performance of millions of children to be educated at public expense, health promotion is a measure of striking economic importance. Reference to the humanitarian aspects of the proposition need occupy little of our time, as the public itself has never been particularly impressed with that argument.

Honesty compels us to admit that the average small community cannot afford to pay for a comprehensive full-time school inspection service. Experience seems to warrant the belief that if all of these communities suddenly found themselves in the market for school physicians and nurses it would be absolutely impossible to find trained personnel to fill the positions created. With a goodly proportion of the twenty-five million school children in the United States totally unprovided for, it is high time for the public to apply itself seriously to the solution of the apparently baffling problems of what to do and how to do it.

Preliminary to venturing a suggestion aimed at the solution of the problems of health of the school child in the small town of rural community, the author will attempt to outline his conception of the purpose or function and scope of the essential school health program. In so doing fundamentals rather than academic refinements will be considered so that it may appear that many important things have been omitted.

The purposes of school health work may be briefly summarized:

(1) To determine the physical and mental status of children of school age to the end that sick and defective or otherwise necessitous children may receive appropriate care and han-

*Approved for publication by the Surgeon General June 21, 1925. Condensed from a paper read before the annual conference of health officers and Boards of Health, Maryland State Department of Health, Baltimore, Md., June 8, 1925.

ding. The provision of such care to the needy unquestionably reacts with benefit to the remainder of a school population; teachers and pupils alike.

(2) To conserve the physical resources and promote the health of the entire school group as the most effective means; to: (a) Build up the resistance of the group to infectious processes; (b) Elevate the standard of school performance; and, (c) Provide the several members of the school population with the bodily stamina needed to successfully meet the demands of school work.

The fruition of such a program will be found in the more normal maturity of the children who graduate from our schools into the broader and more exacting fields of adult citizenship.

The principal difficulties encountered in beginning school health work are occasioned by "Lacks": Lack of community interest, lack of money, lack of trained personnel, and lack of knowledge on the part of most of us engaged in trying to meet the situation as to methods of procedure which will yield the greatest return for money expended. Of these, perhaps, the most significant is the first stated, "lack of community interest."

The Basis of Facts

Full knowledge represents the solution of this phase of the problem. It is inconceivable that the least intelligent of our American communities would deny to its children benefits recognized as necessary to their welfare. It is equally certain that even the most advanced community cannot be expected to proceed on a program involving the expenditure of large sums of money unless it is made to see the need and shown the form in which returns may be expected.

The molding of the public sentiment with regard to essentially constructive measures depends on leadership rather than propaganda. This extremely sententious conclusion, which may be altogether erroneous as so many individual generalizations usually are, brings us to the question: Who shall lead the public to the light? There is no trick in this question. If everyone interested in child health work felt as does the writer the futile discussion for so long indulged in as to the proper administrative relation between health and educational authorities in the conduct of school health work would have had no foundation. There is a big job to be undertaken and for its accomplishment will be required every resource of both

education and health boards. There can be no question of the rights of one as distinguished from the rights of the other. The only rights we need concern ourselves with are those of the children whose growth and development, physical and mental, depend on a complete and harmonious fusion of every community influence.

It is quite natural to conclude that there are parts of a school health program which can be most advantageously administered by the organization whose personnel is trained and experienced in the application of sanitary principles. Likewise, as regards the phases of this work which have to do with the teaching of health principles, the inculcation of habits of right living, and the formation of ideals and attitudes tending to promote personal and community health, the teaching force itself is the instrument of choice.

To admit these contentions is merely to classify types of activity incident to school health work and in no wise diminishes the certainty that if any school health program is to be conducted efficiently there must be mutual cooperation and joint administrative effort between the boards of health and education, manifesting itself actively and continuously through some acceptable system of centralized and unified supervision.

Having hinted so broadly it should hardly be necessary to make the direct statement that this coalition must begin at the very top, in the state government itself, and from this point be projected through the successively less complex units of the county, town, and rural community to the people whose protection and improvement is sought.

Thus we have developed a theory of leadership and have suggested an answer to the question "Who shall lead the people to the light?" It is not suggested that the state assume the burden of school medical inspection in any city or section where this service is being properly administered by existing organizations, nor for that matter in any community able to do for itself. The writer's conception of this proposition relates to the school groups which, unless help is provided from some extraneous source, must inevitably remain without proper health supervision.

The need is for a system of school health promotion applicable to all schools within the group just referred to, and for machinery capable of making its benefits reach the *needy* child in the most humble school in the

most inaccessible part of the district.

The things suggested cannot come to pass in a day and under no circumstances will they just happen. When the public finally awakens to the enormous price it must pay in human disability and economic loss for its neglect the public will in all probability do something about it—unless the public drops off to sleep again before the job is finished. The public, the great body of adult tax-payers, can be led but cannot be "educated" into doing the right thing: that is to say, within anything like an effective time limit.

A natural question arises in connection with the suggestion that the state do for communities, of which it is composed, what these communities are too poor to do for themselves. The practical answer to this query rests on the premise that through centralization and careful standardization of effort the multiplicity of machinery required for the conduct of numerous lesser programs could be eliminated with a great saving of money.

The population of Maryland, exclusive of Baltimore, is roughly three-quarters of a million. One-fifth, or approximately one hundred fifty thousand, of this group consists of children of school age. To reach all of these children for complete physical examination would require more time than any one school year provides and the cost for personnel and transportation would be stupendous. Again we find ourselves face to face with the same stone wall which usually obstructs community effort. The writer is not stubborn enough to attempt to break through, nor agile enough to hop over this wall, but there is a way around. The aim of a school medical inspection service is to secure help for needy children, and in its broader scope to prepare the entire group for future life. This purpose does not suggest that all school children in Maryland or any other state be given a complete physical examination. If there was or were no other conceivable methods of recognizing children who needed help than that of having them gone over with a fine-tooth comb by physicians we would be compelled to join the majority in saying that the job was too big to handle. Of course competent medical inspection is the method of choice and for large centers of population it will forever stand as the only acceptable procedure.

School medical inspection after all is merely a system of screening by which

relatively large bodies of children are classified into two lesser groups, one of which needs attention and another whose physical condition is, at the time of examination, satisfactory. There are two distinct levels even in the professional practice of school medical inspection; one seeks to evaluate the significance of defects observed at examination while the other contents itself with the simple recognition of departures from the physical normal. The first aims at specific correction of abnormalities, the second is for the greater part advisory.

Lacking the admirable fine screening process of the first type of inspection the majority of very needy children can be identified without primary recourse to a strictly medical inspection, not with the thought in view of dispensing with physical examination but for the specific purpose of cutting down the total number of children to be examined, at the same time striking directly at necessitous children in whatever school group or grade they might be found.

The suggestions in this connection do not apply to incoming first grade children. Until such time as physical fitness is made a necessary qualification to admission to school nothing will take the place of competent medical inspection for this age-group. The first, relatively coarse, screen through which children should be passed is that represented by the grade-teacher with whom they are thrown in daily contact. Sympathetic, more than ordinarily intelligent, and when interested, highly observant this teacher is usually quick to sense unfavorable changes in her charges. She has the opportunity that no medical inspector ever has for a series of comparative observations on the group under her supervision. It is not suggested that we make physicians of our school teachers. In using the teacher we are reversing the procedure a physician would follow. In this program of preliminary screening she would sift out the obviously normal specimens, all others automatically falling into the examination group.

With a minimum training the average teacher can test vision and hearing. Not for the purpose of diagnosing eye and ear pathologies but merely to set aside children who see and hear normally thereby diminishing the total amount of work to be done by the inspector or nurse. By observation alone the teacher can single out the genuinely healthy children in her room and it is highly probable that such observation coupled

with a careful estimation of the child's progress in school will spot the children for whom assistance is urgently required. If other signs are needed there are the attendance and age-grade records, both of which have certain value as indicators of sub-normality.

Will this suggestion raise a cry of anguish from the already overburdened teacher. I don't think for a moment that it will and certainly not if it is properly presented. As the physical status of a school group improves the labor of teaching that group is diminished. I have the testimony of teachers for this. It will not be necessary to sell this proposition on the selfish basis of a labor-saving device. In my experience with grade teachers I have yet to meet one devoid of interest in the welfare of her children.

The first step in the coarse screening process is concluded when the teacher has identified the apparently normal children in her group and has forwarded a list of all others, together with her reasons in each instance, to the County Superintendent of Education. The information so secured will pass through regular channels to the central agency designated to complete the investigation of selected cases.

In counties employing a full-time nurse for school inspection work, and even this minimum program cannot be made effective without one such, the second step in the screening process now goes forward. The nurse represents the screen intermediate between teacher and medical inspector. For the final selection of cases for examination, preparation of schools for the visit of medical inspector, in arranging itineraries with dates, and in following up cases designated by the examiner, the nurse will be invaluable.

By the interposition of these two selective procedures it is believed that the actual number of children requiring medical examination in a given school population may be reduced to approximately one-half. In the instance of Maryland the figures drop from one hundred and fifty to seventy-five thousand. We may conclude that there would be a proportionate reduction in professional personnel required and big items of time and money saved. A comparatively small number of school medical inspectors working under state supervision could handle this group.

As regards the character of physical examination indicated for children selected for special attention there

can be no considerable difference of opinion. If there is sufficient indication for any inspection whatsoever the child should be given the benefit of the most searching investigation. While it is advisable to secure a comprehensive physical picture of the child, final diagnosis is not an essential function of the school inspector. In any event the inspector is not the court of last appeals as the local practitioner to whom the family refers the child must have his say. The inspector should keep two points forever before him. Avoid alarming parents. This breeds antagonism. Be positive of the character and gravity of defects reported to parents. When the family physician or specialist fails to substantiate physical findings confidence is lost and corrections lag.

There is no virtue in a system of school medical inspection which does not lead to the improvement of the children concerned. It is impracticable to suggest the provision of clinical facilities for small communities and rural districts but there are forces which can be successfully utilized to combat this deficiency. Even under optimum circumstances clinical corrections cannot be secured without persistent follow-up. Given a staff of district nurses this all important work is rendered remarkably effective as personal contact with parents will win out when all else fails. We are still dealing with stern realities, however, and we can't create such machinery out of thin air.

The three most important existing factors for securing corrections are, First, the grade-teacher, second, the child himself, and, third, the physicians practicing in a community.

(1) *The Teacher*—In the belief that the teaching of health principles is an intrinsic objective of the standard system of education it is suggested that all teachers be thoroughly instructed in these principles and in the correct manner of presenting them. Aside from the inestimable benefit to the children thus schooled in a thorough appreciation of what health really means, there is no more direct way to carry the essentials of right living into the homes.

Given the right attitude toward health measures the classroom teacher represents the most powerful community influence for health promotion.

(2) *The Child*—Once the desirability of physical fitness enters the child's mind it will not be difficult to instill in him a desire for improvement. As far as personal disability is concerned—(Continued on page 886)

A Water-Borne Typhoid Outbreak of Unusual Character*

Where Protection of Property Against Fire Took Precedence Over the Protection of Human Life Against Disease and Death

BY CECIL K. BLANCHARD, ASSISTANT EPIDEMIOLOGIST, BUREAU OF LOCAL HEALTH ADMINISTRATION, NEW JERSEY STATE DEPARTMENT OF HEALTH, TRENTON, N. J.

THE outbreak of typhoid fever in Franklin, N. J., in November and December, 1922, due to the infection of a potable water supply after filtration and chlorination, again proves the danger of connecting a public water supply to any other system containing water unsafe for drinking purposes. The cause and results of this outbreak should indicate to any thoughtful person the folly of giving the protection of property against fire precedence over the protection of human life from disease and death.

Franklin has a population of four thousand and with some reason has claimed to be the ideal mining town of the country. Here is located one of the celebrated mines of the New Jersey Zinc Company, and great efforts have been made to protect the life and limb of the mine employees and to provide proper housing and recreational facilities, a safe water supply, unusual educational opportunities and public health service. The board of health employs a licensed health inspector, who is also the school nurse, and three visiting nurses are employed by the zinc company. The water filtration and chlorinating plant has skilled supervision and its operation is checked by laboratory tests.

The local health department first recognized the presence of an epidemic on November 18, 1922, and immediately requested the assistance of the state department. One hundred forty cases of illness had been estimated with tentative diagnoses of intestinal influenza, pneumonia, and typhoid fever, but no cases had been reported

to the board of health. The physicians were accordingly requested and agreed to submit lists of cases recently attended, with tentative diagnosis of each, thus providing within a few hours a record of all cases of severe illness in the vicinity. This procedure is recommended, as it does not commit the physician to a reported diagnosis at a time when he still may be in doubt, and yet notifies the health department of the cases of suspected typhoid or other disease under investi-

and by a number of the local physicians.

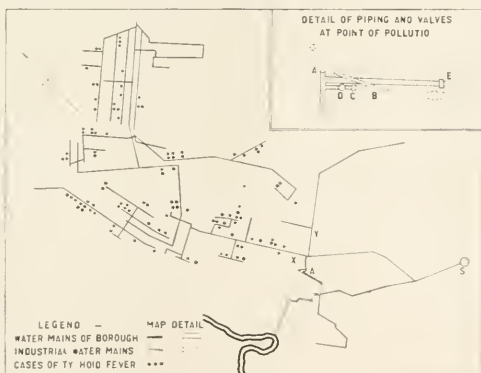

The case histories indicated that the public water supply was the only common vector of infection and that the cases followed the water mains from a point (X) near the center of the town northward. On the accompanying map of the water mains of the Borough and the distribution of cases along these mains is clearly shown. At the point (X) a four-inch pipe extended into the mine yard to a fire

hydrant (A). On another branch (Y) connected to the street main about fifteen or twenty feet south of this point, and supplying a number of houses and a large public school, no cases were reported. The presumptive evidence, therefore, pointed to this four-inch pipe as the probable point at which pollution entered the mains, since the flow past this branch is always northward. Investigation showed that this pipe in the mine yard of the zinc company was connected to a six-inch line (E) containing raw water, drawn from the Walkill River for fire protection purposes. A gate valve separating the two systems was found closed, locked, and covered with dust. A test with dye and one hun-

dred and twenty pounds pressure for two hours failed to indicate a leak at this point.

Extensive excavation in this vicinity (A) later revealed the four-inch pipe mentioned above to be connected to a three-inch line (B) containing raw river water for fire protection and industrial use. The two water supplies were separated in this case by a gate valve (C) on the treated water side of which was a check valve (D) designed to allow potable water to be used in the mine yard but to prevent

gation. Cases were later reported in the usual way.

Water Supply Suspected

While the early symptoms were not typical, there were a few cases which were evidently typhoid. Accordingly, specimens of blood from twelve cases in the third or fourth week after onset were examined at the state laboratory and found to give the typhoid reaction. On November 23 clinical diagnosis of typhoid were made by a pathologist called by the zinc company

Male	77	17	32.1	7.1	26
Female	37	1	22.0	0.6	2.7
Total ..	114	18	15.8

polluted water from entering the street mains. Investigation proved that this gate valve was open, leaving the check valve as the only means of separation between a safe and a dangerous water system. Should this check valve leak, and the pressure of the raw water exceed that on the other system, there was nothing to prevent the pollution of the drinking water for the town with the dangerous river water. A test to prove the valve was at once arranged.

The plan was to introduce a green dye, uranin, on the raw water side of the gate valve (C) set all the valves as they had been when discovered, open the fire hydrant (A) on the treated water system and observe whether or not the green dye passed the valve (D) and colored the town drinking water. Night came before the test was ready for trial, but in the glare of automobile headlights, preparations were completed and the group of health department investigators, company officials, and workmen gathered about the hydrant as the water was turned on. The minute of silence and suppressed excitement was relieved by the gush of a bright green stream from the hydrant. Each witness saw before him the proof of pollution of the town water supply and the presumptive cause of the typhoid outbreak. The theory developed from the epidemiological evidence was fully supported by the conditions revealed by this test. It was later shown by calculation that the pressure on the industrial water system at the point of connection with the filtered supply exceeded the greatest possible pressure afforded by the standpipe (S) so that the flow would always be from the raw to the treated supply.

The conditions just described suggest the wisdom of taking samples for testing a water supply at several points, preferably near the distant ends of the distributing system. All attempts to determine when and for what reason the gate valve (C) was opened and by whom have been unsuccessful, partly due to the critical condition of one of the persons who was best acquainted with the operation of the water system who has not yet recovered from typhoid.

The officials of the New Jersey Zinc Company rendered the greatest as-

sistance and co-operation in discovering the source of the outbreak and applying effectual measures for its control. The company maintained a central office and clearing house for reports, records and information, and assumed entire charge of the hospitalization and home nursing of patients, the care of families afflicted by the epidemic, and the many similar problems which arose daily.

It remained to show the infection of the Walkill River with living typhoid bacilli, to establish a direct route from the infected discharges of a typhoid case or carrier to the mouths of the victims of the epidemic. The river, within a mile and a half above the intake of the industrial supply received the sewage from a primary school of two hundred and eighty persons, from numerous privies located near its banks, and from toilets in the mine and millyard used by perhaps three hundred men. No cases of recent illness suggestive of typhoid were found among the users of the privies along the river bank. On October 12 a child recently recovered from a frank case of typhoid, returned to the school and used the toilet from that date on. On October 9, the father of this child, also convalescent from typhoid returned to work in the mill. It requires less than a minute for the discharge of the school toilets to reach the river and forty minutes for the mill toilet discharge to pass through a septic tank into the river. In either case the organisms might reach the intake within an hour or so from the time they were eliminated. Stool specimens taken from these two persons on December 14 failed to show the presence of typhoid bacilli but this, of course, indicates nothing of their condition in early October.

The dates of possible infection of the river were seven weeks after the onset in the case of the child and eight weeks in the case of the man, and at that stage of convalescence experience has shown that many patients still eliminate the typhoid organisms in enormous numbers. There is good reason to believe, therefore, though it is not susceptible of proof, that the river was infected by one or both of these persons about October 9th to 12th. These are the approximate dates when infection of the pub-

lic water supply would have caused the outbreak.

The distribution of cases by age groups was roughly proportional to the ages of the total population. The distribution of cases and especially of deaths, by sex, however, was the striking feature of the outbreak.

With about twice as many cases, there were seventeen times as many deaths among males as females. If the thirty-one cases and two deaths among boys of sixteen years and under be excluded, there remain forty-six cases with fifteen deaths among adult males, a fatality of nearly one-third.

Music and Health

The positive health of the singer, hard of muscle, abstemious of diet, regular of habit, and tuned to rhythmic response may be contrasted with the hectic life of the average folk who sit cramped at desks during the day, hang to straps in overcrowded cars on their way home, and whose harried existence usually requires the expansion of such small portions of the upper lungs that the effort of deep, full breathing makes them dizzily drunk with oxygen, according to the baritone, Cecil Fanning, in a recent issue of *The Etude*.

On the other hand, a popular notion that is exposed in the same article as untrue in principle and dangerous in practice, is the old belief in the virtues of the singing lesson to develop weak chests and rejuvenate delicate, pale-faced girls. Music teachers well know that picked people, with sound bodies and a penchant for hard work, are the proper candidates for voice culture. Pupils ostensibly ailing can be accepted only on certificate from their physicians, for it is useless, even hazardous, to require persons with weak lungs to do the hard work required in voice culture, and cases of incipient tuberculosis may be irretrievably harmed by it.

Fanning has a word to say, too, of the so-called temperament in singers which is often bad temper merely, or unsettled nerves, and these are ruled out by the regime that results in a good singer, resilient, adaptable, steady, in other words, healthy.

But music, if not musical study, is salutary for all. Its healing powers are utilized for the control of the insane. Shell-shocked patients during the war, oblivious to all other stimuli responded to the therapeutic effect of music. Muscular coordination is achieved through rhythmic motion, and mental health is promoted by means of free expression through music.

Food Legislation and Inspection In Massachusetts

The Historical and Statistical Summary of Food Law Enforcement in Massachusetts is of Particular Interest as Massachusetts Has Been a Pathfinder in This Field

BY HERMANN C. LYTHGOE, DIRECTOR OF FOOD AND DRUG DIVISION MASSACHUSETTS DEPARTMENT OF HEALTH,
BOSTON, MASS.

THE antiquity of state food legislation in this country is but little appreciated by the general public. Shortly after January, 1907, when the Interstate, or so-called United States Pure Food Law became effective, many of my friends said to me, "I suppose the new food law is making considerable work for you." Upon receipt of a negative reply a reason was asked, to which I would reply, "Because Massachusetts has had and has enforced a very good food law for twenty-five years."

There are in the Massachusetts statutes today, laws of greater antiquity than the general food and drug law of 1882. The law upon the branding of chocolate was passed in 1802, the first draft of the milk law was passed in 1859, a law relating to the sale of oleomargarin was passed in 1878, and in 1880 the vinegar law was passed. In 1882 came the general food law based upon the English law and which various other states and the United States used in part as a model for new legislation. The report of the state board of health for 1882 regarding this law states as follows:

A new interest has been awakened in the subject by the action of the National Board of Trade, through whose committee of experts a general bill was prepared "to prevent the adulteration of food and drugs." This bill substantially in the form recommended, has been enacted by the States of New York, Massachusetts and Michigan.

A general food law is not sufficiently explicit to cover all phases of necessary food legislation, and many other laws were passed. In 1887 a law was enacted regarding the labeling of compound lard, and in 1894 a slaughtering and meat inspection law

was passed, which since 1911 in its amended form is operating in a satisfactory manner. In 1896 a law was passed regarding the sanitation of bakeries which was revised and enlarged in 1920. In 1902 the state law regarding the labeling of baking powder was passed, and in 1906, the year of the passage of the United States Food and Drug Act, a general narcotic law, and a law on the labeling of proprietary medicines were enacted. In 1912 came the cold storage law, which has been used extensively as a model for similar legislation in other states.

Additions and Improvements

All of these laws since enactment have been amended usually for the better. In 1901 the general food law was strengthened by the addition of a section prohibiting the use of certain preservatives, unless their presence and percentages were clearly set forth on the label in letters of a certain size. This settled for the time a much vexed question; for, while the law prohibited the sale of food containing ingredients injurious to the health of the consumer, authorities by no means agree as to whether certain of the substances employed as preservatives exert an injurious influence on the system. The amendment waived the question and left it to the consumer to decide whether he cared to assume the risk. In 1916 certain commercial interests presented and succeeded in enacting a bill designed to secure uniformity between the state and Federal laws, although it differed from the United States law in many particulars. This law repealed the above mentioned preservative clause but provides that the department of public health shall adopt rules and regulations, consistent with cert in sections, standards, tolerances and definitions of purity or quality, conforming to the rules and regulations, standards, tolerances and definitions of purity or quality adopted or

that may hereafter be adopted for the enforcement of the act of congress approved June 30, 1906, and the amendments thereof, the said act being entitled, "An Act for preventing the manufacture, sale, or transportation of adulterated or misbranded or poisonous or deleterious foods, drugs, medicines and liquors, and for regulating traffic therein and for other purposes," or now or hereafter adopted by the United States department of agriculture under any other federal law.

The department has adopted such standards and regulations including those relating to preservatives and has successfully enforced them. The validity of these regulations is problematical until passed upon by the supreme court, but from the attitude of persons prosecuted for violating these regulations, it is improbable that the supreme court will be called upon to consider them in the near future.

For ten years prior to the passage of the general food law, the state board of health made numerous investigations regarding the quality of foods and drugs on the market. The act of 1882 provided that the state board of health lunacy and charity should appoint analysts and inspectors; should make all necessary investigations and inquiries in reference to the food and drug supply; should make rules and regulations concerning the collection and examination of samples; and should establish standards not specifically provided for by law. For carrying out the provisions of the act the sum of \$3,000 was appropriated. The law was approved on May 28, 1882, and went into effect three months later; whereupon the board appointed an analyst of foods and an analyst of drugs, who were directed to collect and examine samples, with such assistance as they might require, the appropriation being not large enough to permit the employment of regular inspectors.

The investigations made in the two fields showed that the market was in

1. Owing to changes in legislation, the Massachusetts state health work has been carried on by boards or departments existing under different names. The State Board of Health was organized in 1869. In 1879 it was replaced by the State Board of Health, Lunacy, and Charity; in 1886 it was replaced by the State Board of Health; in 1914 it was succeeded by the State Department of Health; and in 1921 by the Department of Public Health.

TABLE 1.—CHANGE IN CHARACTER OF SAMPLES COLLECTED AT DIFFERENT POINTS.

Character of Samples	1898			1905			1917

*Several.

†Less than one.

a most deplorable condition. In spite of the fact that the law relating to the inspection and sale of milk had been in existence for many years, the milk supply was found to be especially poor, adulteration being almost universally practiced in the cities and large towns. So great was this evil that in the following year, 1883, the legislature amended the act by increasing the appropriation to \$5,000, with the proviso that two-fifths of the whole should be expended in enforcing the milk law. Accordingly, two additional analysts were appointed, whose sole duty it was to look after this part of the work.

Owing to the conditions found by the several analysts to exist in their different fields, the legislature of 1884 made further amendments of the food and drug act, the most important of which increased the appropriation to \$10,000, whereof not less than \$6,000 should be devoted to the enforcement of the laws relating to milk and milk products. This enabled the board to appoint regular inspectors, who, by law, were clothed with all the authority given to local inspectors.

The character and extent of, and the geographic, climatic, and seasonal variations in food adulteration is little realized by those not actively engaged in the work relating to this subject. The character of the work of the department in the enforcement of these laws has inculcated a wholesome respect for the law in most people doing business in this state. There is, therefore, very little adulteration of food

and drugs in comparison with other localities where the inspection is not so thorough or so uniform. That the vendors of foods and drugs know that eventually their products will be examined by this department has a great influence toward improving the food and drug supply of the state. The history of the department shows that little by little the food supply has been improved, until at present the work, with but few exceptions, may be compared with the policing of a law-abiding community. It has been found necessary from time to time to change the character of samples collected, as the need of inspection decreased. This is best illustrated by the table, compiled from the reports of the department for 1898, 1905, and 1917.

In 1898, 67 per cent of the food samples consisted of condensed milk, coffee, cream of tartar, cocoa, chocolate, honey, molasses, and spices. In 1905 the character of these foods improved to such an extent that but 30 per cent of the samples collected were of this class, and in 1917 conditions had further improved so that only 3 per cent of the samples examined were of this class.

Of the total samples collected in 1898, less than 1 per cent had to do with foods commonly treated with preservatives; in 1905, 35 per cent of the samples were of this class; while in 1917 the number had fallen to 6 per cent.

Of late years more attention has been given to decomposition in foodstuffs, and during 1917, 27 per cent of the total food samples collected were

examined with this in view, while in 1898 and 1905 practically no work was done of this nature. The increase in examinations for decomposition is due principally to recent advances made in the chemistry of food decomposition.

The Spoilage of Food

The spoilage of food is unfortunate, to say the least, and in many instances is caused entirely by the greed of dealers in foodstuffs. Investigators of the division indicate the use to a certain extent of rotten meat in sausages which are so highly spiced that the nature of the meat is not noticeable to the consumer. This meat can be purchased much cheaper than fresh meat. The cause of the spoilage of the meat is found one step nearer the producer. The butchers who supply the sausage manufacturers with such meat are obliged to buy cattle from the farmers, not when they desire to purchase, but when the farmer desires to sell. If the price of beef is low, the butchers, hoping for a rise in price, will hold the carcasses until such time as the meat is unfit for sale at retail, and they will then sell to the sausage manufacturer. In one sausage factory a large quantity of rotten meat was confiscated, and a sample of sausage intended for sale was obtained. This sausage was so highly seasoned that the odor was perfectly normal, although the analysis showed that the decomposition had proceeded to an alarming extent.

Much of the decomposed food formerly found in cold storage was due to the false impression that rotten food may be placed in cold storage, and in some mysterious manner the process will make the articles satisfactory. Many instances are on record where dealers have held food too long at a high price against a falling market, and have placed the deteriorated articles in cold storage to be held until the next season. Salmon placed in storage on July 7, or thereabouts may be cited as an example of such practice. Delayed freight shipments are responsible in a measure for considerable of the decomposed food on the market. It becomes the duty of the department to confiscate such articles. A carload of decomposed smelts offered for storage had been one month in transit from the Pacific coast. About six years ago eleven carloads of miscellaneous fish were confiscated by reason of decomposition caused by congestion of freight en route from the Pacific coast. This fish was in such shape that it would have been impossible to dispose of any of—(Continued on page 920)

Report of Progress in Public Health Laboratories

So Much of Prevention Depends Upon Laboratory Findings that News From the Laboratory Assumes a High Import

By IRA V. HISCOCK, ASSISTANT PROFESSOR AND HOWARD J. SHAUGNESSY, INSTRUCTOR, DEPARTMENT OF PUBLIC HEALTH, YALE SCHOOL OF MEDICINE, NEW HAVEN, CONN.

DURING the past thirty years there has been a gradual development in the applications of laboratory methods to public health service,¹ which has resulted in more precise knowledge of the nature of disease and in practical measures of prevention. Health officials now recognize the laboratory as the foundation of all effective health work and as a means for coordinating their activities. In fact, around public health laboratories centers the practice of modern medicine.

Laboratory service in the large cities is well developed and specimens are annually examined at a rate which corresponds to about one to every twelve people. It is a direct and welcome service, usually free, which tends to make friends for the health development among physicians and the people. The lack of laboratory facilities in rural districts, however, has handicapped the practice of medicine, particularly in those areas far distant from state laboratories. Many capable young graduates stay in cities where better facilities exist, and rural communities suffer accordingly. The movement in several states, as Iowa, Michigan, and New York, to extend laboratory and hospital facilities on a state-wide basis is most gratifying; and it is believed that the public as well as the medical profession will soon be convinced of the importance of such measures.

The municipal health department laboratory movement has grown so rapidly that in the recent study by the American Public Health Association² it was found that all of the eighty-three cities surveyed in 1920

had some form of laboratory facilities. The usual types of service consist of bacteriological and chemical examinations of water and milk,—and in state laboratories frequently of sewage to determine the efficiency of treatment plants; examinations of food (including in some cases shellfish); occasionally of drugs, and of beverages for alcoholic content; examinations for diphtheria, tuberculosis,

who, by the way, are responsible for many important modifications in our standard procedures, to accept new methods. Inadequacy of funds and personnel, however, make conservatism imperative, although there is obvious danger through this practice of overlooking valuable aids in diagnosis.

There has been a tendency in many public health laboratories, often due to reasons just cited, to neglect chemical measures, reliance being placed entirely upon the microscope or the agar plate. A recent article by Gage and Earle³ among others, suggests the possibilities of chemical methods in examination of blood, urine, and other types of specimens, for diagnostic or treatment purposes. It is interesting to note, in this connection, a statement by Dr. Coon, health officer of Bridgeport, to the effect that the city laboratory has made arrangements to do work in blood chemistry. "We are never-

The mobile laboratory has many advantages in handling epidemic conditions, and water or milk problems in camps or remote districts. Louisiana, Wisconsin, and Indiana have used the traveling laboratory with uniformly good results.

theless, proceeding cautiously and slowly that we may determine just how far this work may profitably and advantageously be carried on in laboratory practice." The tremendous value of accurate acidity and alkaline measurements has also been generally realized by the large laboratories, and resulted in the adoption of hydrogen-ion concentration measurements. This technic, together with other advances in physical chemistry, has opened up new avenues of promise in nearly all branches of laboratory work.

Changes in technic and in the type of examinations performed necessarily come slowly in city laboratories and few innovations are adopted. Routine laboratories are urged from time to time by their neighbors in research,

the mobile laboratory has many advantages in handling epidemic conditions, and water or milk problems in camps or remote districts. Louisiana, Wisconsin, and Indiana have used the traveling laboratory with uniformly good results.

In many routine laboratories the personnel consists of a bacteriologist who can Gram stain satisfactorily or detect diphtheria organisms in culture, or a water chemist whose chief activ-

ity is confined to the differentiation of the various types of nitrogen as free ammonia, albuminoid ammonia, nitrites and nitrates and to the calculation of oxygen consumed. Of course, there is need for that type of service, and the prevailing rates of remuneration do not usually attract the skilled biochemist, or stimulate a large group of laboratory workers to secure this higher training. New lines of service have developed, and as research has increased in quantity as well as quality, there has arisen a demand for more highly skilled personnel. Consequently, it is hoped that the salaries and opportunities of trained laboratory workers will become more favorable in the near future.

In the past and to some extent in the present, library facilities have often been lacking and the books have been limited to a pitiful half dozen, bolstered up by a copy of standard methods. Technical journals—the inspiration for new methods—have been confined to personal copies. New methods have been learned at the infrequent conventions or through the kind offices of some old classmate. Several laboratories are now equipped with the leading public health and medical journals and also give their technicians either the benefit of research or visits to conventions and other laboratories where new methods are being developed.

Research Work Increasing

It is encouraging to find that research work is increasing in both city and state laboratories, and that nearly one-third of the municipal laboratories studied in the survey previously mentioned were pursuing definite lines of research in 1920. A laboratory if adequately staffed and equipped, is in a position to render important service to its own community as well as to the country as a whole, through its research studies of practical problems.

As illustrations of the prominent part which public health laboratories may play in research fields, through the kindness of several laboratory directors and health officers to whom we gratefully express our thanks, it is possible to refer in this summarization to specific work which is now in prog-

New methods are learned chiefly at infrequent conventions or through the kind offices of some old classmate. This picture shows visiting students and nurses in the blood room of the laboratory at Marquette University at close of recent hospital convention in Milwaukee.

ress or has recently been completed.

(1) *Diphtheria*.—The New York City laboratories' under the direction of Dr. Park, are now working on the monthly injection of guinea pigs with stored toxin-antitoxin to discover when the antigenic power of the vaccine is lost and how the toxicity compares with the antigenic power. Every public health worker is familiar with the important contributions of the New York laboratories in standardizing the technic for the Schick test and toxin-antitoxin immunizations, and in demonstrating the value of such immunizations in the saving of human lives, especially in childhood. The Milwaukee laboratories have also been engaged during the past year in observations on the Schick test and toxin-antitoxin immunization, from the standpoint of practical application of these measures in the city. In the Massachusetts state laboratory, an investigation has been made of the mechanism of the pseudo-reaction in the Schick test. In this work, reported by Dr. Nye at the April meetings of the American Association of Immunologists, various substances present in diphtheria toxin have been isolated and their effect studied on individuals who have given pseudo or combined Schick reactions. Studies have also been made of diphtheria immunization in horses; and on the relations between toxin and antitoxin in diphtheria toxin-antitoxin mixture. Obviously, only thoroughly equipped, well manned laboratories can undertake problems of this character.

Another phase of diphtheria control in which the laboratory has participated is the determination of virulence of diphtheria bacilli. In 1915 Zingher and Soletsky⁷ introduced the intracutaneous method of making diphtheria virulence tests, which differs from the subcutaneous method in that the cultures, after isolation are grown on solid medium, suspended in salt

solution and injected into the skin of a guinea pig. Havens and Powell,⁸ and Force and Beattie⁹ later described the whole-culture virulence test which tended to show that this method would be advantageous in dealing with cultures from convalescents, contact carriers, and carriers at large, for

tests can be made with the original diagnostic culture, and the necessity of isolating pure cultures is eliminated, and the whole culture instead of one or two random plate colonies is represented. Bull and McKee⁶ gave further observations with the method on the basis of cultures obtained in a survey for carriers among the school children of Baltimore, 3,995 cultures being considered.

Improvement in Technic

Considerable work has also been done by Mr. Bransfield at the Bureau of Laboratories of the Connecticut State Department of Health on comparison of the use of the whole culture with the pure culture in testing diphtheria organisms for virulence by the intracutaneous method. The whole culture has been found by him practically as reliable as the pure culture for virulence tests by this method and has the advantage of simplifying the test so that it may be more generally used in the administrative control of diphtheria. The Bridgeport laboratory also reports success in reducing the time required by earlier technic to determine the virulence of diphtheria cultures. According to information furnished by Dr. Stokes of Baltimore, the laboratory of that city is investigating the percentage of diphtheria virulence tests among various types of carriers, and also studying selective media for the detection of the diphtheria bacillus.

(2) *Scarlet Fever*.—Studies in the etiology or treatment of scarlet fever have been carried on in several laboratories, notably Detroit, Grand Rapids, Milwaukee, Bridgeport, and New York.

(3) *Tuberculosis*.—The complement fixation test has been further studied in Boston; method of sterilization of sputum before examination, in Detroit;¹⁰ while in New York certain suggestions as to removing the "wax" from tubercle bacilli and so making a

better vaccine have been tested. Comparisons between different methods of staining for the tubercle bacillus have been made in Baltimore.

(4) *Syphilis*.—Modifications of the Wassermann reaction or new complement fixation tests have been described particularly by Kolmer¹¹ and by Kahn,¹² and several laboratories have pursued studies along one of these or independent lines of research. Studies made in the New Haven Hospital by Drs. Fox and Sanderson¹³ are especially interesting for they considered both clinical and laboratory findings. Problems in connection with the Kahn precipitation test for syphilis as compared with the Wassermann test have been studied in Boston, where the gonorrhea complement fixation test has also been given consideration. In Chicago, studies have been made of the effect on the Wassermann reaction of traces of alcohol, phenol and water which may be introduced from syringes and needles used in collection of blood. Among the subjects under investigation in Baltimore we also find (a) comparison of routine Wassermann with ice box complement fixation test and Sachs-Georgi method, and (b) a simple apparatus for the collection of serum for examination for the treponema pallidum. The Massachusetts state laboratory has studied the Kahn and other precipitation tests in comparisons with the Wassermann test; the antibody content of serum of syphilitics during treatment; the turbidity of antigens; and the occurrence of the Wassermann reactions in pregnant women of various social groups.

(5) *Milk*.—Research studies of milk in Boston include comparative counts, using various media such as milk powder, beef extract, beef infusion, and various methods such as the Frost plate, Breed, and Slack methods. Other milk studies include: (a) staining of Frost Little plates and comparison of various milk and water media, in Detroit; (b) investigation of certified milk farms for streptococcus carriers in Chicago; (c) the comparison of standard media with other media suggested for milk work in Baltimore, in addition to studies on the sterilization of milk bottles; and (d) studies on pasteurization and tuberculosis in Milwaukee; and (e) studies of bacterial counts on milk

bottle caps with comparison of effects of different methods of capping in New Haven.

(6) *Water Supply and Swimming Pools*.—The laboratory in Chicago engaged in studies of the virulence of *B. welchii* in the city water last year, while in Milwaukee, an investigation was made of taste producing bodies in the water supply, as well as studies of water-borne infections and tests of the efficiency of domestic filters with or without ozone. The Baltimore laboratories studied the correlation of the neutral red reaction in fermentation tubes with the various types of intestinal organisms in water, and the relation of residual chlorin in the city water supply to the typhoid rate. In addition to extensive work on filtra-

In testing the protective value of pneumonia serum, dilutions of culture of living, virulent pneumonia germs are prepared for injection into white mice. Bacteriologist shown making such solutions.

tion methods at the Lawrence Experiment Stations, the Massachusetts laboratory has carried on a large amount of work to determine the usefulness of hydrogen-ion determinations, in various forms of water purification, especially where coagulants are used. The sanitary and laboratory conditions of swimming pools were investigated in Boston; Dr. Pryer of Detroit reports a partially completed study of d'Herelle bacteriophage in the treatment of swimming pool water; while Chicago also carried on experiments on swimming pool disinfection. Milwaukee made a sanitary survey of bathing beaches.

(7) *Miscellaneous*.—In addition to the above mentioned investigations, many other types of problems have been studied. These include work on food poisoning, especially the association of *B. botulinus* with food poisoning, as in Detroit and Milwaukee; laboratory diagnosis of typhoid fever

in Richmond; (a) drinking glasses at soda fountains, (b) spread of mouth-borne infection by the telephone mouth-piece, and (c) methods of detecting traces of carbon monoxid in air in Chicago; (a) a new colony counter, (b) a generating apparatus for the disinfection of rooms or other closed spaces with hydrocyanic acid gas, (c) methods for growing the Gonococcus, with observations on the length of time, the organism lives on different media, (d) benzol poisoning, and (e) a report on the hazards from the use of manufactured gas in Baltimore; (a) Vincent's angina and (b) pneumonia in Milwaukee; and (a) the further study of the filtrable viruses obtained from persons suspected of influenza and from persons having other respiratory diseases, and (b) more theoretical work on agglutinins and precipitins, studying methods of absorption and of group affinities, in New York. Finally, should be mentioned the research studies in the Massachusetts laboratory by Fellows of the International Health Board on (a) means of increasing the yield of serum for therapeutic and diagnostic purposes; (b) purification of vaccine virus by means of ether extraction; as well as investigations concerning the production of trade waste and sewage purification; and coal analyses.

Dr. Wadsworth, director of the New York state laboratories, writes that "In order to insure complete and permanent records of all research undertaken in the laboratory, outlines of proposed work together with reviews of the literature are submitted for criticism and approval. Reports summarizing the work done are made every month. This material constitutes the scientific file which is maintained by the library staff for reference. The educational value of this procedure to the scientific staff of the laboratory has been apparent from the beginning. It has been an important factor in the development and training of the research workers.

"I should like to emphasize that all the research work done here is undertaken with a view to the distinct practical bearing which the results will eventually have on public health laboratory work as a whole."

At the New York state laboratory some research is always in process, having—(Continued on page 922)

Northwestern University to Have a New Teaching Hospital

NORTHWESTERN University has been a large contributor to the alleviation of human suffering resulting from disease. The medical dispensary last year gave assistance to some forty thousand patients, while thousands of visits by the school's social service department were made to homes of the sick. The present buildings of Northwestern University Medical School at Twenty-fifth and Dearborn Streets, Chicago, have served for thirty years and were long since outgrown. The buildings are inadequate. The school's museum of pathology, one of the finest in the United States, cannot be properly displayed or fully utilized. Laboratories have to serve as lecture rooms, and, in spite of the

\$5,750,000 have been contributed toward the building fund, to which a gift of \$600,000 from the General Education Board is contingent upon Northwestern obtaining \$1,400,000 for endowment alone. The following facts regarding the project, and regarding health work in general, are given out by the University in its recent pamphlet called, "The Last Battlegrounds of Disease":

Rising to a height of sixteen stories,

its dispensary service, and at all times to assist physicians in keeping in close contact with advances in research and practice.

To erect such a plant, with a teaching hospital, a clinic, a dental school, and a medical school, will cost several millions of dollars. The work cannot all be done at once, but it is the hope of the University gradually to develop on the campus one of the greatest urban educational institutions in the country.

The pamphlet abounds in statistical information regarding health. On any given day it is said that three persons out of every hundred are ill. In Illinois 200,000 persons are on the daily sick list; in the United States, over 3,000,000. It costs the United States a billion dollars annually to be sick, or nearly a million dollars an hour. If preventive medicine could every where be practiced, nearly

Architect's drawing of what new Alexander McKinlock Memorial Campus of Northwestern University will look like when completed. The main building will house hospital, medical, and dental schools. The law and commerce schools will occupy separate buildings. The University is now nearing achievement in a five million dollar campaign to erect the first units of what eventually will be the tallest university building in the world, and one of the nation's largest urban campuses. The location will be on nine acres of ground on Lake Shore Drive at Chicago Avenue, Chicago.

fact that throughout the middle west physicians are imperatively in demand, applicants for medical training are turned away in large numbers.

The new medical school, to be located on a nine acre tract on Lake Shore Drive, will carry as its necessary concomitant a teaching hospital, designed by James Gamble Rogers, the architect who was responsible for the famous Harkness Memorial Quadrangle at Yale. To date more than

and with its Gothic tower surmounting the whole, the proposed school will be as some great cathedral of Europe with the University Law and Commerce Schools nestled beneath it like the houses of its bishop and its priests. With the possible exception of the medical school on the bay at Rio de Janeiro, the Northwestern Medical School will be unsurpassed in the beauty of its site by any such institution in the world. Moreover, in its new location the school, when completed, will be able to serve the North Shore section of Chicago, to increase

50,000 deaths could be prevented annually. In twenty years the mortality rate has been reduced 47 per 10,000 persons. If in the next two decades one-half as great a reduction can be brought about, each year the lives of over 200,000 persons who would ordinarily die can be saved. "The time may come when it will be a crime to let a patient die before he is 75 years of age from a preventable or curable disease," the pamphlet concludes.

Immunization By Ingestion

The New Theory of Immunization Introduces the Protective Agent Through the Same Route the Virus Follows in a Normally Infected Organism.

BY A. BESREDKA, PROFESSOR IN THE PASTEUR INSTITUTE OF PARIS, PARIS, FRANCE.

WHEN it was discovered that the blood of those who have recovered from an infectious disease, and have thus become vaccinated, contains anti-bodies it appeared at first that the problem of immunity held no more mystery for us. When, furthermore, the first facts of antidiaphtheric serotherapy were known, the immunization of animals against viruses of all sorts went forward so rapidly that in the space of a few months the pharmacopeia was enriched by a multitude of sera.

Following close on serum therapy came the prophylaxis of the communicable diseases. Numerous vaccines against cholera, plague, the typhoid and paratyphoid infections, dysentery, and the like were recommended on all sides and applied on a vast scale.

The development of vaccine therapy, though of more recent history, has followed the same course and has been applied in the most diverse diseases. It has, as we know, been particularly successful in infections due to the *Staphylococcus* and its beneficial effects have not failed to be attributed to the presence of specific antibodies. The benefits derived from such antibodies can hardly be estimated. It was therefore very natural that in them alone should have been found salvation, the master key to the edifice of acquired immunity; active as well as passive.

It is true that difficulties have been met with and failures recorded. Thus the hopes based on an anti-microbe sera,—typhoid, cholera, staphylococcus infections and the like,—have not been realized. But this has not prevented microbiologists from seeing in the antibody the most powerful weapon against infectious disease. Even in our day it is toward the intensive production of antibodies that all the efforts of preventive and curative medicine are bent.

Is it not time for a reaction against this tendency? This is a question we have asked ourselves from the time of our first studies on experimental typhoid fever.¹

It may be permissible here to recall

the investigations, now become classic, of our master Metchnikoff in regard to inflammation and natural immunity. For him it was morphological elements alone which took part in the battle of disease,—the phagocytes and the microbes. This conception which after the discovery of antibodies seemed too exclusive a one today appears to us to be the conception which dominates the greater part of the manifestations of immunity. Is it not indeed probable that what is true of natural immunity is also true of acquired immunity? If in natural immunity the conflict is between the phagocyte and the microbe with no place for a third factor, the antibody, why should we admit that a different condition obtains in acquired immunity and that in this latter instance the antibody plays a preponderating role?

We can scarcely conceive that in nature there exist two distinct mechanisms of defense, one cellular, operating in natural immunity and one humoral in acquired immunity. Such a sharp line of demarcation shocks our conceptions of the continuity of biological phenomena. The basis of this study lies in the absence of antibodies in natural immunity while they are always present in the course of artificial immunity. But is it sufficient to demonstrate their presence, to infer that the antibodies form the basis of artificial immunity, and that without them it would not exist? Are we not in this case victims of the adage "*post hoc ergo propter hoc*"?

It is true that cases have been reported where this parallelism between the manifestation of immunity and the appearance of the antibodies has been lacking but it was said that these were exceptions that confirmed the rule. Thus faith in the overwhelming importance of the antibodies has not been shaken. We ourselves based all our thinking on this idea for many years until the day when a new fact made us doubt this role of the antibodies. This new fact was involved in a study of anthrax, and it has made necessary the complete revision of certain chapters in the theory of immunity.

As everyone is aware the anthrax bacillus is one of the most pathogenic of microbes for laboratory animals, and the guinea pig is particularly susceptible to its attacks. Numerous investigators have sought to confer upon the guinea pig an immunity against this deadly malady but without success. With the utmost effort all that has been accomplished has been to make it possible for the guinea pig to survive a fatal dose, not of the original virus, but of the second vaccine. What is the reason for this difficulty? It has been generally assumed to be the extreme sensibility of the animal with respect to the particular bacterium in question. On the contrary our experiences, of which the full exposition would involve too many details for summary in the present paper, have shown that the assumption of the unusual sensibility of the guinea pig is incorrect. Furthermore they have made it clear that this animal can be as easily vaccinated as the sheep or the cow.

In studying the mechanism of susceptibility in the guinea pig we were led to the apparently paradoxical conclusion that the guinea pig is actually resistant to anthrax. In fact when one inoculates this bacillus into the peritoneal cavity or the tracheal canal or even into the subcutaneous cellular tissue the guinea pig remains uninjured. Let us hasten to add, it remains uninjured only on condition that in the course of these various inoculations one takes care to avoid breaking the skin. As soon as the skin is broken death is inevitable. In contrast to all the other organs which are resistant toward anthrax, the cutaneous tissue, and it alone, is receptive in the guinea pig.

In the light of this discovery we resumed our attempts at vaccination; only instead of proceeding by subcutaneous or intraperitoneal inoculation as is the usual practice, we sought to vaccinate the guinea pig through the most susceptible tissue, that is by the skin. Our reasoning was simple. The guinea pig is highly resistant to anthrax. In order that this resistance may become complete it is only necessary to vaccinate the

1. Ann. d. l'Inst. Pasteur, March, 1911, 194.

skin. Once this is accomplished the whole animal should become refractory to anthrax. Exactly this result has been achieved. In producing a cutaneous vaccination we have realized a cutaneous immunity and once this cutaneous immunity was established the animal could be inoculated by almost any route. From a high natural resistance the guinea pig has been raised to a point of practically perfect resistance. It may be added that we have been able to assure ourselves of the entire absence of antibodies in the blood of the guinea pigs thus vaccinated. We were then dealing beyond question with a case of strictly local immunity.

Vaccinate Receptive Organ

This was the point of departure for all the investigations which we have since carried on in regard to local immunization and immunity. It was clear that before attempting to vaccinate against any infectious disease it was necessary to discover which is the receptive organ in that disease. All later efforts should then be directed toward vaccinating the particular organ in question by introducing the active substance by the same route which the virus follows in a normally infected organism. By this course one should be able to realize a maximum immunity with minimum effort.

This principle has already found application in a certain number of infections due to *Staphylococci*, *Streptococci*, *Bacillus pyocyaneus* localized in the skin and the bony system. In the present article we wish to dwell solely on those diseases which affect the intestinal tract, dysentery, typhoid fever, and cholera.

It is obvious after what we have said in regard to anti-anthrax vaccination that in this case it was the oral route which was indicated. Our own experimental studies as well as all other available information indicated that in these infections the organ which is primarily receptive is the intestine. It is made clear by these investigations that the Shiga bacillus, the typhoid and paratyphoid bacilli, and the cholera vibrio exhibit a remarkable affinity for the wall of the intestinal tract. Whether these microbes are injected into the peritoneal cavity, the blood stream, or even the subcutaneous tissue, they always direct themselves toward the intestine and it is always there that one recovers the infecting organism frequently in a state of purity. For all these infections the intestinal wall occupies the same relation that the skin does in the case of anthrax. To

bring the vaccine into contact with the intestinal wall in a manner at once direct and safe there is evidently but one method,—oral administration.

So much for a priori reasoning. Our first experiments, however, did not encourage us to persevere along this path. Investigations on laboratory animals failed to give favorable results, the direct ingestion of the vaccines seemed to be powerless to produce an immunity against subsequent inoculation of a fatal dose of the virus. We now understand the reason for these failures. It appears that to bring the vaccine into intimate contact with the receptive cells of the intestinal tract, preliminary treatment is necessary. Under ordinary physiological conditions these cells are protected by a layer of mucus. This mucus interposed between the receptive cells and the virus which penetrates by mouth into the intestine guards the organism against infection and at the same time eliminates the possible effect of the vaccine. In order to give free play to the vaccine we thought of the possibility of utilizing bile. In the attempt to obtain the desired effect we were not counting merely on the addition of a small quantity of ox bile to the bile already nominally present. The addition of ox bile does much more than this. It has the power of intensifying normal biliary secretion of the animal (homo stimulation) it increases the peristaltic movements of the intestine, it removes the mucous surface. In short, it brings about a preliminary cleansing of the intestine which makes it possible for the receptive cells thus exposed to come into immediate contact with the vaccine, to be impregnated with it, and thus to become armed against a new attack.

This preliminary sensitization by the use of bile is indispensable, as our experiments demonstrate, when one attempts to vaccinate against the bacteria of the typhoid-paratyphoid group or against the cholera vibrio.² It is not necessary on the other hand in the case of anti-dysenteric vaccination, the Shiga bacilli being capable themselves without artificial aid of desquamating the internal surface of the intestine.

A Single Receptive Agent

If the mechanism of vaccination against typhoid, dysentery or cholera is that which we have described how does it happen that by the methods ordinarily employed, that is, by subcutaneous injections, such good suc-

cess has been obtained in vaccinating against these maladies. In our opinion the mechanism of vaccination is the same in both instances. Let us recall that in all the diseases with which we are dealing there is only one receptive organ, the intestine. In virtue of the affinity of all these viruses for the intestine the microbic substances which compose the vaccines are invariably carried toward their organ of predilection. The vaccines may be injected into the blood, into the peritoneum, under the skin or at any other point in the organism,—their real efficiency is manifest only from the moment when they enter into combination with the receptive cells, that is to say, from the moment when they arrive in the intestine. Vaccines injected subcutaneously therefore act in exactly the same way as those introduced by the mouth, though obliged before arriving at their destination to pursue prolonged travels through the body. The subcutaneous vaccination requires a longer time to act; obliged to traverse various tissues each of which retains a part, these vaccines arrive at their goal somewhat weakened.

Principle is Established

Furthermore since they give rise to antibodies useless in the specific defense reaction these subcutaneous vaccines operate at the cost of a general reaction which it would be far better to avoid. There is no doubt that the subcutaneous route can be used for vaccination against diseases of the intestinal tract, but between this quite roundabout and sometimes dangerous procedure and the oral method which has no drawbacks, while presenting the same advantages, our choice should be clear.

A large number of oral vaccinations have been conducted in recent years nearly all in the case of typhoid and paratyphoid. Their harmlessness is today solidly established. Such vaccinations have been carried out in infants, in pregnant women, in undernourished subjects, in subjects presenting definite contra-indications with respect to subcutaneous vaccination. No trouble has ever been noted sufficient to interfere with the continuance of their usual occupations by the patients and it appears clear that immunization by the oral route being powerful locally, that is to say limited to the intestine, can be established without the participation of any other organs of the body. In a recent epidemic in the course of which a considerable number of persons were un—(Continued on page 932)

² Very recently Messrs. Leger and Boury have shown that the same thing is true for oral vaccination against plague.

The Adolescent Girl Becomes a Health Asset to the Home

The Founding of Mothercraft Courses. New Bedford Schools Evolved a Solution for a Prevalent Social Problem

BY HUGH GRANT ROWELL, M.D., FORMER DIRECTOR OF HEALTH AND HYGIENE, SCHOOL DEPARTMENT, NEW BEDFORD, MASS.; NOW LECTURER AND ASSISTANT PHYSICIAN IN TEACHERS COLLEGE, NEW YORK CITY.

WHETHER in a school system or in executive work in a broader health program, the administrator must constantly keep himself reminded of the actual needs of his clientele and shape his departmental activities to meet them. That it is no easy task at times is most obvious. That the interdepartmental wall must be broken down, that every organization possible need to be utilized to accomplish a given end is self evident. The subject of this paper involves an apparent solution, at least in part, to that very serious problem—infant mortality.

Come through any congested district and notice the child mothers. As soon as one child can toddle, another frequently occupies the cradle. The tiny place of abode soon teems with small irresponsible humanity and it devolves upon the older children to assist the overworked mother in all possible ways. Should the mothers as well as the father work outside the home, the difficulty becomes even more acute. This problem is encountered in any city of any size.

The type of population may form some factor but if it does it is only in that the newer the immigrant is to the country, the greater the need of definite help.

Granting good municipal health programs, including prenatal clinics and care, intelligent obstetrics, pre-school clinics including those for the modification of milk, there is still a big gap left.

Two definite phases are noted: (1) Is the home care of the baby intelligent? (2) What happens in cases of sickness in the family? Hospitals and

clinics care for the urgent cases when disease exists. But this is an age of preventive medicine and who is to care for that side? What of minor but incapacitating illnesses? What of convalescences? District nurses cover their work well, but what of the hours they can not spend on a given case? Who is to care for the situation then? The answer lies in

might almost be considered homicidal. Therefore any instruction, if only partially successful, is at least a step in the right direction. Several sources for this exist.

Courses may be given by semi-private organizations; they may be given through public institutions, commonly the schools; or the two forces may unite as was done in New Bedford. In good cooperation, the last method offers great possibilities. That mothers can use the same instruction is obvious but the belief exists that the growing generation represents more hopeful soil.

In schools, the work may represent an actual course in the curriculum, either required or elective, and is usually placed in the junior or senior highs or special schools. If time can not be available otherwise, a splendid start can be made by a volunteer, after-school course, and the only difficulty will be to find accommodations for those who desire to take it. This was tried in New Bedford this year, the Mothercraft Course being used. The equipment was largely

made by the school sewing classes and the rest purchased, the expense being very nominal. The New Bedford Women's Club yearly plans some definite sort of health work for their contribution to the schools and after a course of training for several months by a graduate nurse of unusual skill in this work, certain club members took charge of several classes and made an instant success as teachers.

the various courses in infant welfare or child hygiene (whichever term you prefer) and in home nursing. These will be discussed in the broader sense with some reference to local methods as possible object lessons.

First considering the child welfare; obviously if a brief, practical course could be given to groups of mothers' helpers, the methods being those approved in hospital circles, the assistance would be more intelligent and the results less dangerous. Methods prescribed by grandmothers may be good at times; at other times they

Interest in child welfare problems grows with the acquisition of skill in devising ways and means to care properly for the child. And graduates of Mothercraft classes are not slow to utilize their skill in their homes.

made by the school sewing classes and the rest purchased, the expense being very nominal. The New Bedford Women's Club yearly plans some definite sort of health work for their contribution to the schools and after a course of training for several months by a graduate nurse of unusual skill in this work, certain club members took charge of several classes and made an instant success as teachers.

Public interest was thoroughly aroused and good support was given by the papers. On the evening of the

graduation of the first group, exercises were held including demonstrations of the work, reading of essays, a short graduation address by the school director of health and hygiene, apt remarks of a practical nature by the superintendent of schools, and presentation of diplomas and buttons by the president of the Women's Club assisted by the class teachers. A large crowd attended, including members of the school board, and this combined with splendid newspaper write-ups placed the work on an absolutely stable plane for the future.

A word about the Mothercraft Course. It is the product of years of unselfish work by Miss May Bliss Dickinson of Boston, a former nurse and public health executive and has the advantage of brevity, clarity, and thorough planning. Originally tried in Massachusetts under the auspices of the Federation of Women's Clubs, it has spread through the country and at present seems to be at least as popular and well-approved as any course. A small book called "Children Well and Happy" contains the material and it is well presented. For the purpose for which it is used, it is of the utmost value. This represents a start. Previously certain courses had been given under other auspices, but I think most persons will agree that such matters under school auspices offer best possibilities if for no other reason than better facility and greater accessibility of students.

In a high school or special institution a more ambitious course may be desirable with greater equipment, depending largely on local necessities.

A definite step of great importance is the introduction of this work into continuation schools for the girls of fourteen and fifteen. In New Bedford last year we introduced it and made it a required subject, offering a course totalling forty hours, about one-third being infant welfare and two-thirds home nursing. This may

seem brief but the time in such schools is only a very few hours per week per child. The course is flexible and somewhat regulated by needs discovered through two hours' home visits a day as part of the duties of the teachers and trained nurses.

This continuation school group not only represents those who may well care for some of the children after working hours but they are also to be considered the prospective mothers of a few years hence, since this group marries early. Actually they are probably the most hopeful group of all from a public health point of view since they are thus early started on

becomes the solution to many minds. To others of us, a better solution may be a pretty universal understanding of the rudiments of home nursing by the growing girl, regardless of her social status. In this connection I believe that each trained girl of this type is actually a missionary into the home, and others may learn from her.

To humanize the idea, just imagine yourself for a moment sick and dependent upon your family for nursing. Supposing your body for some reason was very tender and every jolt hurt. Then imagine an untrained person hauling you about to change the sheets, to give you various comforts that are needed, perhaps to move you about with every move a moment of agony. What then would be your gratitude to have some one in the house or family who through the lessons of the home nursing course was able to do these things for you with a minimum of discomfort. One can conceive of wills being changed under such circumstances.

The subject matter of all of these courses is obvious, yet a few

All activity is education, but of particular use is specific training in providing comfortable and hygienic conditions under all circumstances. Their practicality accounts for the very human interest all the girls display. These high school girls are the home-makers of tomorrow.

the right path toward good health.

Home nursing courses are high school and special school subjects. High school here is to mean both junior and senior. That more advanced institutions teach this work as well is also true. The continuation school side has been brought out.

These courses represent a solution to several difficulties. Most of us realize that the profession of nursing is no longer attracting as many young women and many of those who do take the training soon go into public health work for reasons which it does no good to mention. Such being the case, nurses are and will be a considerable expense for the sick and may be scarce and hard to secure as well. This being true, the training of practical nurses, so-called (the present day practical nurse is often called much harsher names),

ideas may be mentioned—undressing the baby, bathing the baby in the various ways, simple modifications of milk of the type prescribed for home modification by physicians, clothing the child, preparation of makeshift cradles from baskets with improvised mattresses as well, using common household articles—this for infant hygiene. For home nursing we think of care of the bed, including choice of material, handling the patient when the bed is changed with an actual lifeline dummy for practice, bathing the patient in bed, sickroom arrangement, diet, preparation of diet trays, and precautions in the event of contagion. The prerogatives of the skilled nurse are encroached upon in no way likely to lead to danger or confusion, and yet the baby or the patient is bound to be benefited.—(Continued on page 927)

State Subsidies for Maintenance of County Sanatoriums*

Under Minnesota Scheme State Aid Has Meant Better Business Management, Standardized Records, With Adequate Medical Supervision, and Improvement of Service Throughout

By ROBINSON BOSWORTH, M.D., EXECUTIVE SECRETARY, ADVISORY COMMISSION OF THE STATE SANATORIUM FOR CONSUMPTIVES, ST. PAUL, MINNESOTA.

THE tuberculosis sanatorium movement in the United States has been active during the past twenty years. Starting out almost exclusively as a state sanatorium movement, modern thought and experience have gradually evolved the present widespread county sanatorium system.

State sanatoriums have been established in numerous communities and we believe always for the reception of "early," "incipient," or most "favorable cases" of tuberculosis. While state sanatoriums have in the main been filled to capacity and in some states need has arisen for more than one state sanatorium, the percentage of incipient cases admitted has not reached that point anticipated or hoped for.

From our observation of statistics from numerous sources we gather the fact that incipient, or early stage cases, comprise about 17 per cent of the total attendance in most institutions intended by law to be exclusively for this class. The moderately advanced comprise between 40 and 50 per cent of the inmates.

A true appreciation of tuberculosis and the many problems relating to its control and eventual eradication immediately stamp it as a "community problem" in the fullest sense of the term.

Twenty years ago it was recognized as a foe worthy of the energies of the state, hence, the state sanatorium.

In fact, there were many who have considered the problem one for the national government to attack.

While changes have gradually taken place in the minds of those best informed regarding hospital and sanatorium facilities for the tuberculous, this change does not include any hint that the tuberculosis problem is any

ternational Congress in 1908, "that the most important feature of the movement to control tuberculosis must be hospital care for the advanced cases and sanatorium care for the early cases—these two requisites could be effectively provided only by locating institutions near enough to the homes of the patient so that they would readily avail themselves of their benefits."

Many states have gone far in carrying out the above recommendations through the establishment of numerous county sanatoria.

In many of these states the public was strongly of the opinion that the state should supervise local county sanatorium activities against tuberculosis. In the more advanced communities not

only was state supervision demanded but state financial assistance was sought and obtained.

Financial aid in the form of subsidies granted to assist in the construction or maintenance of local county sanatoriums associated with state supervision is the greatest demonstration of the fulfillment of the state's obligation in a fight so large and so many sided as to warrant its being classed a community problem.

State aid is granted apparently for two purposes: (1) To encourage and promote the building and use of many sanatoriums by counties, (Mass.)¹ (2) To stimulate construction of many

1. Special report of the Massachusetts Department of Health relative to tuberculosis in the Commonwealth, and state, county, and municipal hospitals, January, 1923, p. 62.

Patients' cottage at Glen Lake Sanatorium, Hennepin County, Minnesota.

the less a problem of the community than was the opinion when sanatoriums were strictly limited to state institutions. On the contrary, legislation has been adopted in numerous states establishing state supervision over activities directed against this disease which would indicate that the public is strongly of the opinion that the resources of the state, as an aid, are required and should be with logic employed.

Many Small Institutions

The modern tendency is toward the establishment of numerous institutions serving communities of limited area and population—the county sanatorium. This is directly in line with recommendations adopted by the In-

*Read before the National Tuberculosis Association, Santa Barbara, Calif., June 20-23, 1923.

View from south of Riverside Sanatorium, Granite Falls, Minn.

sanatoriums and insure high standards of construction and maintenance.

Most of the states in which laws authorize counties to establish and maintain tuberculosis sanatoriums have not seen fit to assume any obligations, such as, cooperating with the county, either financially or supervisory.

Among a total of 41 states replying to a questionnaire requesting county sanatorium data, 26 states authorize sanatoriums: One state, Minnesota, grants aid toward construction (up to \$50,000 for any one sanatorium); nine states grant state aid toward maintenance. The amount of state aid varies from \$7.50 per week per free case to three dollars per week, with a limitation in one state of three thousand dollars annually to an institution.

Those states granting financial aid are listed in Table 2.

It was the intention of Minnesota to assist the counties by paying an amount equal to one-half the total cost of caring for a free patient, but as conditions have changed, increasing the maintenance cost, the five dollars per week received is nearer one-fourth the cost. In Michigan, the amount paid is one-half the cost of maintaining the sanatorium but must not exceed three thousand dollars.

Referring to possible intentions on

the part of the law-making bodies in granting state aid we must take into account several circumstances. In Missouri, \$7.50 is paid, the highest in the country, it was evidently a financial assistance, pure and simple, intended to stimulate establishment and to help carry the burden—this for the reason that no supervision on the part of the state was included. It

from the state department of health requested and received by the Massachusetts legislature include the elimination of all further state aid on the ground that as the total annual deaths from tuberculosis are now exceeded by the total number of beds available for tuberculosis the original purpose of the subsidy would seem to have been attained.³

There seems to be no desire to in any way influence in the future the type of institution, either as to its physical features or its management by making state aid dependent upon high standards, else the above recommendation would not have been made.

It may be impolite to remark further that other comments offered

by the state department of health to the Massachusetts legislature might not have been possible had previous state aid been based upon standards of construction and management for we note the following: "From a thorough study of the matter it appears that certain of the municipal

institutions lack both personnel and equipment sufficient to accord with what are considered adequate standards for the hospital treatment of tuberculosis."⁴ "The cost of maintenance at the county tuberculosis hospital—(Continued on page 930)

Floor plans of Patients' cottage at Glen Lake Sanatorium.

was not granted to assure high standards in construction or management.

In Massachusetts aid was granted for the purpose of stimulating the establishment and use of county sanatoriums and it is of great interest to learn that recent recommendations

Purified Oysters

BY WILLIAM FIRTH WELLS, BIOLOGIST AND SANITARIAN, NEW YORK STATE CONSERVATION COMMISSION, ATLANTA, NEW YORK.

SHELLFISH naturally thrive in tidal estuaries draining the fertility of the continent. Here are the most favorable conditions for the multiplication of the myriads of minute plants and animals on which they feed. It is unfortunate for oyster culture that these estuaries are also valuable harbors, about which population concentrates, and pollutes the tidal waters. Thus many of the finest grounds are restricted by public health regulations, and so any efficient and reliable method of purification should concern sanitarians as well as the shellfish industries. During the past year the first practical plant has been certified by the New York State Conservation Commission, thus, it is believed, marking the end of the period of preliminary study and the establishment of this process as a part of the oyster industry. Fifteen thousand bushels of oysters have been purified commercially, marketed with the approval of the authorities, and consumed by an appreciative public.

Tests Confirmed

Since the operation of this plant represents the consummation of successful scientific, commercial, and administrative studies, a brief review of the development of the process may have a public health interest. The underlying principles were carefully worked out during 1914-1915 at the Fisherman's Island, Va., experiment station in charge of the writer, serving under Surgeon General H. S. Cumming, U. S. Public Health Service, then in charge of the investigations of coastal waters. It was discovered that shellfish closed tightly in the presence of considerable excess of free

chlorin, thus protecting the interior tissues from its effects, but permitting the sterilization of everything exterior to the shells; and secondly, that shellfish kept in pure salt water rapidly eliminate by their natural functions all interior contaminating materials accumulated on the tissue surfaces. A process of artificial purification based on these principles was described in *Public Health Reports*, July 14, 1916. (Reprint 351).

the process. Cooperative experiments, carried out in August and September, between the U. S. Bureau of Chemistry, the U. S. Public Health Service, the State Conservation Commission, and the city department of health, and witnessed by the state department of health, were described in *Public Health Reports*, April 22, 1921 (Reprint 362. Meeting at the invitation of Conservation Commissioner George D. Pratt, official representatives of these

Federal and city authorities, together with the U. S. Bureau of Fisheries, accepted the results as demonstrated, and endorsed the process, subject to official supervision by the conservation commission and inspection of the product by health authorities. A set of requirements embodying these findings was drawn up by the commission, and, after approval by the authorities, was adopted, and offered to the committee of growers.—*Fishing Gazette Feb., 1923.*

Mr. G. Wilbur

Doughty, a member of the committee, convinced that the process offered a practical solution of the problem, immediately applied for assistance in constructing and operating a plant. The detailed account of the efforts of Mr. Charles R. Bettes, engineer, the Electro Chemical Company, the General Electric Company, the U. S. Public Health Service, and the State Conservation Commission in perfecting the installation and operation of this plant, and the results of the laboratory tests, very generously made by the Federal Bureau of Chemistry and the New York City laboratories, and inspection by the state department of health, are of more particular interest to the sanitary engineer. It is sufficient to state that

Oyster purification plant established by Sprague & Doughty at Inwood, L. I. Farther basin full; near basin filling; pump and electrolytic cell in house at left. Infiltration trench runs from bulkhead to house back of basins.

During the summer of 1916 further confirmatory tests were made, and in the fall the process was tried out under commercial conditions, at Jamaica Bay and New Haven Harbor, in conjunction with Dr. Payne B. Parsons of the U. S. Bureau of Chemistry. No technical difficulties arose under these conditions, and the process was therefore pronounced a practical measure.

In April, 1920, Senator Royal S. Copeland, then Commissioner of Health of New York City, entertained a hearing of oyster growers to consider such sanitary measures as might serve to enable certain New York waters to be continued in oyster production. A committee of growers, there elected, requested the state conservation commission to demonstrate

Oyster purification plant, Inwood. Interior of control house, showing electrolytic cell (1) and rectifier (2).

before the plant was certified, shellfish were handled as economically as in floats hitherto, that control was as simple and direct as an automobile, and that the tests far surpassed existing standards.

The following description, extracted from the 1922 annual report of the New York state conservation commission, may serve to confirm these statements.

Inwood Plant

The oyster purification plant, which has been successfully constructed and has received the certificate of the commission, is located at Inwood, Long Island, and is owned by Messrs. Sprague and Doughty. The general features of this plant are as follows: Two concrete basins, each twenty-two feet by twenty-five feet by eighteen inches deep, with a capacity of six thousand gallons each and each capable of handling two hundred bushels of oysters. Water is obtained from a gravel-filled trench near the basin. It is salt water derived from Jamaica Bay and has salinity of 1.021. Pump of one hundred twenty-five gallons per minute capacity. Sterilizing agent, hypochlorite of sodium produced by electrolysis of the sea water. A portion of the water pumped passes through an electrolytic cell (Electro Chemical Company) and thence returns to the pump suction and is mixed with the inflowing water. The strength of sterilizing solution is controlled by regulating the amount of current entering the cell. An eleven-point switch on the rectifier used makes this operation one of great simplicity.

Restrictions on Process

Oysters to be treated by this process must be reasonably free from mud and organic contamination and must

not, when first placed in the basin, score over five hundred. They may be brought within these requirements by previous treatment. Water used must not be grossly contaminated with sewage or other filth, must be reasonably clean and, before chlorination, must not score over 5 (five portions of the water sample to be treated as five shellfish in securing this score). It may receive preliminary treatment. Salinity must not be less than 1.014.

Process.—The object of this process is to sterilize the outside of the oyster and to allow it, by natural processes, to free itself of such infected material as may be in its shell or body cavities. These voided materials are then removed or sterilized. The edible portion of the oyster is not exposed to the action of any chemicals; the animal is merely allowed, in a perfectly natural manner, to wash itself clean in sterile water. In detail the process is as follows:

(1) Oysters of suitable cleanliness are placed in a clean empty basin. One bushel of oysters requires twenty-five gallons of tank capacity. Oysters must not be in layers over eight inches in depth and must be so arranged that the water can freely circulate about them.

(2) The basin is filled with water showing, by ortho-tolidin test, an excess of free chlorin. Amount of chlorin regulated by experience to meet the following requirement.

(3) Sterilizing interval; during which there must be more than 0.2 parts per million of free chlorin in the water. Starting when basin is completely full, lasts for thirty minutes, or such longer period as may be necessary to reduce the free chlorin to less than 0.5 parts per million.

(4) Drinking interval. Starts at end of previous interval and lasts for at least six hours. During this interval the oysters are expected to be open and active.

(5) Basin is drained.

(6) Basin refilled with chlorinated water as in (2).

(7) Sterilizing interval; same as (3).

(8) Drinking interval of not less than twelve hours.

(9) Oysters removed, basin drained and cleaned.

Supervision.—This process is not difficult to carry out and the cost is so low as to make it commercially practicable. It is evident that successful results depend on the care and intelligence of the operator and the commission will certify such plants only after it has passed on the qualifications of the person in responsible charge.

Saferguards.—Severe restrictions as to the quality of the water used, the degree of pollution of oysters which may be subjected to this process and the qualifications of the responsible operator are imposed by the commission. In addition the nature of the process is such that there is a large factor of safety to offset any irregularities in the treatment. As the meat of the oyster is not touched by chemicals, a stronger dose of chlorin can be used than is possible in the sterilization of drinking water; actually ten parts per million of free chlorin are developed in the water entering the basin, an amount that would make water undrinkable and which is about twenty times the dose ordinarily given to potable water. It has been found at Inwood that with this dose of chlorin in the influent water, the water in the basin, when full, contains between one and two parts per million and that during the subsequent thirty-minute sterilizing interval this falls to between 0.2 and 0.5 parts per million. If for any reason this reduction does not take place, the sterilizing interval is prolonged until the chlorin content is below one-half part per million. It is thought that this process is more thorough and more certainly effective than any to which other foods are subjected, except those which are completely sterilized, as in certain canning processes.

Results Obtained.—Results which have been obtained at Inwood are shown below, the numbers in each case being the "score."

Water of the Bay.....	50-500
Untreated water from trench.....	5
Water entering basins.....	0
Untreated oysters.....	50-500
Oysters after first drinking interval	5-50
Oysters after final treatment	0-5
Allowable score for marketable oysters	50

Solved by Concerted Effort

Only by the united efforts of the oystermen, the health authorities and the commission could this process successfully be established. Acknowledgment is gratefully made for the aid freely rendered the commission by Messrs. Sprague and Doughty, the U. S. Public Health Service, U. S. Bureau of Chemistry, New York City Department of Health, the individual officials and employees of those bodies, and the manufacturers of the special equipment used.

The sanitary significance of this process should be apparent to those

familiar with the history of water and milk supplies. Improvement has not been limited to protection of the watershed or dairy. Higher sanitary ideals have been made possible through positive methods of removing chance infection. The cases are becoming more exceptional where original purity in water or milk guarantees the safety insured by purification or pasteurization. Likewise, it is becoming increasingly difficult to protect shellfish from natural contamination. The waters are always free for navigation, and, in the act of harvesting, are plied by dredge boats. Only if accumulated foreign materials are eliminated can shellfish really be considered "certified."

True conservation demands the constructive development of all legitimate means of utilizing most fully our natural resources. The intrinsic importance of food producing resources is daily becoming more apparent. An increasing population must hesitate before unnecessarily condemning fertile shellfish farms.

Results of Sanatorium Treatment in Germany

Reiche (*Beitr. z. Klin. d. Tuberk.*, Vol. 51, p. 210) presents data in regard to after life of 1866 tuberculous patients receiving sanatorium treatment during the decade 1895-1904. In 1921 only 35 per cent of these patients were dead and 47 per cent were fully self-supporting. This remarkably good record is made possible by the fact that more than half the cases were in the incipient stage when admitted.

Pathology and Diagnosis of Manganese Poisoning

The ingestion of manganese oxid (by cats) results, according to Schwarz and Pagels (*Arch. f. Hyg.*, Vol. 92, p. 77) in a marked increase in the number of red blood cells and in hemoglobin content. Later a change in a reverse direction was sometimes manifest. The authors suggest that workers in manganese should be subject to blood tests and that those who show abnormal results in either direction should be given very careful medical examination.

Bakers' Eczema

Tankard suggests that potassium persulphate, contained in some flours, is the cause of bakers' eczema. Water when added to flour containing this chemical produces an acid reaction thought to be responsible for the

skin troubles. In the shop where this investigation was carried on trouble was experienced only in that part of the bakery where the flour contained persulphate, the flour under investigation showing 6.3 parts of potassium persulphate per 100,000. (*Lancet*, Aug. 11, 1923, 5215, p. 279).

How to Keep the Inside of a Tent Cool

The Bureau of Standards has devised means for keeping the inside of balloon hangars at as low a temperature as possible. As the same methods are particularly interesting as means for keeping the inside of tents cool, and for keeping down temperatures in any cloth covered enclosure, and are useful in a reverse way for getting the greatest amount of heat from heating appliances, the process is given herewith:

If the outside of the tent is covered with a highly reflecting substance as white paint, while the inside is covered with aluminum paint, the radiation into the interior will be reduced by at least 78 to 81 per cent. The reason why this method of painting has this desirable effect is that white paint reflects the sun's rays while the aluminum paint is a poor radiator of the long-wave heat rays. Of course, it must be remembered that this scheme for painting tents would have just the reverse at night and would prevent the heat on the inside of the tent from escaping into the cooler air outside.

This same work proves that aluminum paint is the poorest possible kind of a coating for heat radiators in houses, at least from the point of view of obtaining the greatest amount of heat from a given surface, since aluminum paint has a tendency to keep the heat inside and not allow it to escape into the room.

Botulism Epidemics

Botulism has been known for centuries in parts of Germany, where it was called "sausage poisoning," but the germ was not discovered until 1895; and no cases of it are known to have occurred in the United States until about 1909. Since then, according to a bulletin recently published by the U. S. Public Health Service, ninety-one single or group outbreaks of botulism have been reported in the United States and Canada. A total of 345 persons have been affected, of whom 213 have died, giving a case mortality of 61.7 per cent.

Of the ninety-one outbreaks only thirty have been proved bacteriologically or toxicologically to be due to botulism, the others being so adjudged from the symptoms. About two-thirds of the outbreaks (25 proved and 38 not proved to be botu-

lism) were caused by plant food, and about one-third (5 proved and 14 not proved) were caused by animal food.

The following products have been proved or assigned as the particular food in which the germ causing this disease developed in the cases investigated: String beans, home canned 17; commercially canned, 3; corn, home canned, 9, commercially canned, 1; asparagus, home canned, 5; apricots, home canned, 3; pears home canned, 2; spinach, home canned, 2, commercially canned, 6; beets, home canned, 1; commercially packed, 2; liquor home brewed, from old home-canned products, 1; cottage cheese, home prepared, 2; pickled mackerel and herring, home preserved, 1; ham, home cured, 2, commercially cured, 1; sausage, home prepared 1, commercially prepared, 2; salt pork, home cured, and beef products, home prepared, 3; minced olive relish, commercially canned, 3; ripe olives, commercially pickled and bottled, 7; pork and beans, commercially canned, 1; tomato catsup, commercially bottled, 1; clam juice, commercially bottled, 2; tuna fish, commercially canned, 1; evaporated milk, commercially canned, 1; and minced chicken, commercially prepared, 1.

It is to be noted that spoilage due to botulism germs cannot always be determined by the appearance or odor of the food.

The Common Drinking Cup

While the common drinking cup has been banned by law, it persistently reappears and awaits the coming of the ignorant or thoughtless person or the care-free child. The common drinking cup may be avoided for esthetic reasons, or because of a knowledge of its potential dangers; but with all its repulsiveness it is uncommon to find the finger of suspicion pointed at one particular cup as the cause of a certain case of disease. An instance of this kind, however, is reported as follows in the current issue of *Public Health News*, the monthly bulletin of the department of health of the state of New Jersey:

At a country club a thirsty golfer used the glass setting beside a water faucet. As soon as he was through with it an imitative child used the same glass. Later it was found that the golfer at the time was developing typhoid and the child developed the disease about two weeks after using the glass. It was only because the club was not entirely public and the people there were known one to another that any suspicion could be directed toward the glass which had been provided to spread nothing more than refreshment.

Accident Prevention and Health Service in Industry

Sperry Gyroscope Company Accident Rate Less Than Two Per Month Per Thousand

By M. R. LOTT, PERSONNEL SUPERINTENDENT, SPERRY GYROSCOPE COMPANY, BROOKLYN, N. Y.

THE company had accepted an order for a special machine which the customer required by a given date. Work was progressing according to the schedule laid out by the production control department but it was considered advisable to speed up the machine work a little to allow more time for assembling and testing the completed product. The foreman of the lathe department picked John Jones to do some of the most important of this urgent work because Jones was a careful dependable man, quick and accurate in his performance and always ready to respond wholeheartedly to any appeal from the foreman to help out on an emergency job. It happened, however, that John Jones had a little indigestion when he came to work in the morning, he did not feel sick enough to see his family doctor or to stay at home, but he did not feel comfortable. However, when the foreman brought the rush job to him, he dug into it with his best

efforts and made good progress at first, but the headache that had set in, developed rapidly. There was no ready relief available for there was nothing at the factory in the way of medicines except a first aid kit containing a few bandages and a little iodine. Jones kept up in spite of the pain but he could not keep his mind on the work so when a big piece of the metal turning curled up around the lathe tool, he absent mindedly took his hand to brush it away and suffered a severe cut on the wrist, which meant no work for John Jones for the rest of the day nor for the

days while his hand was useless.

Such experiences have been common in industry. They stand for suffering and decreased earnings on the part of the employee, as well as delayed production for the company. But can such happenings be avoided? Can such waste be reduced? The experiences of the Sperry Gyroscope Company and other organizations that have studied these occurrences and have provided adequate health service,

cured to devote his entire attention to eliminating the sources of danger as far as possible and to the education of the workers to think and act along safety lines. One of the first moves was to establish a plant hospital, to secure a nurse, and then a physician.

Immediately the lost time accidents dropped at an amazing rate: in fact they were decreased in seven months from a peak of forty-five cases per month per one thousand employees to two per month per one thousand employees. This showing has been generally maintained, and the accident rate still further diminished until we show a record for 1923 of only three lost time cases which involved a total of only 148 working hours and none of them was subject to compensation payments.

The questions may be raised, how has this record been accomplished? How does health service affect the accident record? How much does such service cost? In answering the first of these questions it may be

With physician and nurse in daily attendance, and service available for every emergency, both injuries and illnesses have attention sufficiently early to be effectual in by far the greater percentage of cases.

show results that are surprising in their effectiveness.

Before the Sperry Gyroscope Company had its health service or made a serious effort along the lines of accident prevention, the lost time cases due to accidents reached a peak of forty-five a month per one thousand employees. This situation was reached during the summer of 1917. There was no organized personnel department at that time, but as the accident conditions appeared to the management so unnecessary, for the business was in no way a hazardous one, a competent safety engineer was se-

lected of interest to explain something of the organization, facilities available, and methods used.

The work forms a part of the regular activities of the personnel department and is in charge of a safety director who works under the general supervision of the personnel superintendent.

The Safety Director is responsible for securing and maintaining safe and healthful working conditions for all employees and of this work the health service and minor injuries take a most important place. A nurse is in constant attendance and a com-

petent physician is available at the plant for one hour each day and subject to call at any time. Too much cannot be said concerning the importance of suitable personality in the people who render this service. Their attitude towards the employees with whom they come in contact may make or break any effort of the company to improve conditions.

Adequate facilities are provided for the first aid treatment in the plant hospital which is located in a light airy place convenient to the elevators and to the street. The equipment is not elaborate, there are no regular hospital beds, for there are well organized hospitals near the plant where arrangements have been made to care for any serious cases that might occur. A small room, however, is provided with a cot and facilities for the comfort and use of men who, need rest and quiet as a temporary condition, and an examination room is also available.

While the medical and first aid service is readily and freely available and employees are urged to take full advantage of them, it has been found necessary to have all treatments authorized by the head of the department in which the patient is employed. A simple form is used for this purpose, provision being made for a statement of the nature of the case, together with the time and cause of any injuries which may have been sustained. This establishes data for use in compensation cases and prevents the safety director from overlooking opportunities for correcting unsafe conditions and practices. These authorizations are made out in triplicate for all cases. The original is presented to the nurse and signed by the patient; the duplicate copy is retained by the department head for all cases involving loss of time, and forwarded to the safety director when the employee returns to work; the triplicate copy is forwarded to the safety director for his information and investigation.

The nurse maintains a daily register of all sickness and accident cases, together with the diagnosis, explanation and treatment. The new cases are separated from the re-visits and the information from this daily register is transcribed to individual record cards for reference purposes.

Whenever subsequent treatments are considered advisable, the nurse gives the patient an appointment slip to insure his return at the proper time.

It has been found advantageous to keep a continuous analysis of the nature and cause of all accidents as well as for the diseases and disabilities. A simple means is provided for this purpose through a weekly report form

under the heading of sickness and unknown reasons, that proper assistance may be rendered as needed. Cases of absence for more than three days duration, and for which no reason is known are investigated through home visits.

In reply to the question, "Does health service pay?" The experience of the Sperry Gyroscope Company makes it possible to state—that it does. For example, during the severe influenza epidemics occurring during the past few years, the company experienced only three per cent loss of attendance among its employees due to the prevailing illness. Then again there is the proof that the service which forms a part of the accident

prevention work, has formed an important part in the reduction of the number of accidents and their severity. As previously mentioned, prior to the organization of such service, the lost time accidents reached the rate of forty-five cases in one thousand employees per month but with accident and sickness prevention work, this rate was diminished with surprising rapidity to less than two per month, in 1922 there were only three cases involving a loss

Under the old regime, when accidents just "happened" and causes remained unstudied and uncorrected, the peak shown of 45 per thousand employees per month was typical; now the rate for both accident and sickness is less than two employees per thousand per month. The saving is enormous, and the cost inconsiderable, in view of the improved conditions.

which lists the items of analysis desired. Columns are provided for recording each day the number of cases charged against a particular item, distinction being made between the new and the re-visit cases. Such a record indicates the common causes of disabilities and aids materially in planning for their elimination.

In connection with her routine duties, the nurse makes a daily canvas of all departments to determine the absentees, and from the information secured, she compiles an absentee report, segregating the names of employees away from the plant, according to the cause of absence: (1) Sickness or unknown. (2) Vacation or leave of absence. (3) Part time or lack of work. A close follow-up is maintained over the cases appearing

of time during the entire period. Not only have the accident cases diminished in their number but the severity rate has also attained a low figure as shown by the following.

The number of days lost, per one thousand hours worked during the year are as follows: 1918, 1.936; 1919, .316; 1920, .055; 1921, .087; 1922, .013.

An investigation of the relationship between the number of sickness and accident cases treated in the plant hospital shows that for 1922, 55 per cent were sickness.

During the year 1922, with six hundred employees, the medical expenses amounted to \$286 per one hundred of pay roll. These expenses include salaries of plant physician and nurse, outside consultation fees, and medical supplies. If consideration is

given to the cost of the safety organization other experience has shown that the inspection service, bulletins, membership in the National Safety Council amount to \$.156 per one hundred dollars of pay roll.

These facilities and services have been found to be a profitable investment as the costs are small in comparison with the advantages secured. They have enabled the company to carry its own workmen's compensation insurance with considerable financial savings, at the same time providing better and more prompt attention to the needs of employees and their families. The employees and their families profit with the company through the steadiness on the job, and much suffering has been eliminated.

Many States are Educating Civilian Cripples

When in 1920 the federal government first embarked upon aid to state enterprise in taking care of and re-educating civilian cripples, only six states were engaged in that service. Under the stimulus of federal assistance thirty-four states are organized to avail themselves of this aid, and two more states have recently passed favorably upon it. On June 30, 1922, in thirty-one states the work was actually in operation. During the fiscal year 1920-1921 the states reported having handled 3,893 cases; during 1921-1922 17,089 cases were reported. It is estimated that at present organized care in the several states is provided for about fifteen thousand cases.

As federal appropriation to this service is provided for only up to July 1, 1924, the groups who are interested in the expansion of this work are uniting to urge Congress to continue the federal appropriations for this purpose.—*The Survey*.

Shape of the Hand in Various Occupations

Brezina and Lebzelter (*Archiv. f. Hyg.*, Vol. 92, p. 53) present a set of anthropometrical measurements of 1,200 workers belonging to different trades which indicate certain characteristic differences in the dimensions of the hand. The ratio of hand-breadth to hand-length is between 45.9 per cent and 46.9 per cent for blacksmiths, locksmiths, foundrymen, transport workers and bricklayers but falls to 43.8 per cent for employees of the postal-savings service and to 43.3 per cent for typesetters. The authors of course point out that such differences are no doubt largely due to

selection rather than to the influence of the occupation itself.

California Sterilization Law to Undergo Test

California laws provide for the sterilization of epileptics, habitual criminals, feeble-minded and incurable tuberculous persons, on discretion of the state prison board and the state board of medical examiners, but have not been enforced because of unwillingness on the part of authorized officials to assume the responsibility. A test in the supreme court of the state will soon be undertaken at the instance of Judge Robinson, who declares enforcement is demanded by the increase in subnormal persons, of whom there are 18,000 in state prisons, insane asylums, and schools for the feeble-minded.

A one-year course of training for nursing housekeepers is planned by the University of Saskatchewan in cooperation with the provincial Red Cross and the Graduate Nurses' Association. The course is to be established in such government-aided institutions as do not already offer a regular three-year nurses' course.

English Reports on Atmospheric Pollution

The eighth report of the Committee for the Investigation of Atmospheric Pollution contains systematic analyses of observations on atmospheric pollution from thirty experimental stations in different parts of Great Britain. Comparisons are made between the observations of the current year and for five year period preceding the report, and between summer and winter deposits. Photomicrographs of some typical specimens of impurity magnified up to two thousand diameters are given in the report and a useful bibliography is appended on the various methods of measuring dust. The report deals exclusively with measurement, not with mitigation.

Health Centers Needed for Indians

There should be health centers and visiting nurses on all Indian Reservations as there are elsewhere, urged Robert J. Hamilton, president of the business council of Blackfeet Indians on the occasion of the midwest conference on Indian Affairs held in Chicago, September 25 to 27, and the Indian girls themselves should be trained in health work to their own people. As Indian affairs are at

present administered, stated Mr. Hamilton, there is no efficient system of medical survey. Medical control should be under the control of the U. S. Public Health Service, not a function of the Bureau of Indian Affairs. Nowhere is reorganization more necessary than in the administration of Indian health. A group whose wealth amounts to sixty billion dollars, including oil land, timber, mineral wealth, and personal property, he said, should be able to command complete health protection.

Chicago Takes Census of Hard of Hearing

According to a study just completed by the University of Chicago, there are approximately seventeen thousand men and women in Chicago who are totally deaf. For six years the Chicago League for the Hard of Hearing has offered free employment service, education, and recreation to hundreds of these people. Mr. Frank H. Shepherd, formerly director of rehabilitation work in Oregon, has been appointed director to carry out plans for a greatly broadened program of activity in the interests of deafened persons in Chicago.

The Paris correspondent of the *Journal of the American Medical Association* writes that scandals growing out of medical service to war veterans have been so flagrant that a bill has been proposed in the Chamber of Deputies looking toward the creation of an Order of Physicians analogous to the previously established Order of Advocates.

The proponents of the bill contend that public interest demands that physicians be, by legal enactment, grouped together in an organized "medical corps," which shall be accorded the right to impose penalties on "undesirables" in the profession without waiting for scandals to become public. The impossible penalties range from a simple reprimand to permanent cancellation of the license to practice medicine. For each district over which the sphere of influence of a school of medicine extends, the bill will establish a regional medical council, to which offenders would have the right to appeal.

The state legislature of Michigan has passed a bill providing for the extension of Mother's Pension to families in which the father is suffering with tuberculosis to a degree that prevents his gainful employment.

Boston Visualizes House of Health

NOT content merely with maxims of health, the Boston Health Show exhibited as one of its most popular attractions the objective signs of hygienic practice as they evolve in daily home life. The first section, the Doctors' Office, showed cut-outs picturing doctor, and mother, and child. The rooms were equipped with stethoscope, forceps, basins, sponges and other paraphernalia. The lavatory was of the most approved type, a hospital bed neatly made, the scales, baby basket, and other articles suggest the proper routine for the child. The mother's needs were specifically anticipated by posters on the wall bearing the titles: "Your baby is sick and will need close watching." "Your baby is gaining splendidly." "What a lot of nice things you have ready for the baby." "These are the things you need ready for home care." "Examination shows the urine clear." "Your blood pressure is normal today, only 120." "Your blood pressure is 160. You must see the doctor at once." "Examination shows albumin in urine. See the doctor at once."

In the parents' bedroom the nurse is bringing the babe to its mother, who is in one of twin, four-poster beds drawn close to open window. Posters serve to convey the information that the infant sleeps alone, that it is breast-fed, and that in regularity of habit lies the mother's comfort and the baby's safety. Even the matter of birth registra-

tion is urged in picture language.

The nursery was fitted with sleeping basket, woolen sweater and brown sleeping bag; enamel table, with bathing accessories; pitcher and towel; absorbent cotton in glass receptacle; powder in shaker; soap, towels, and clothing properly arranged for use. In the center was a portable rubber bath tub, and on the side stand a round enamel receptacle for soiled clothes, and an enamel "baby's toilet." A thermometer silently pleads for attention to temperatures, and the usual insistence upon milk as food, cleanliness, and medical supervision was made.

Two metal beds were in the children's sleeping room. The bureau with mirror, the vase with flowers, and the candlestick gave the air of simplicity and beauty the place demands, and other appurtenances emphasized going to bed at seven, sleeping alone, and keeping windows open.

In the bathroom a child brushed its teeth. Wash cloths, soap, and other conveniences were at hand, and the usual admonition to cleanliness was carried in the "Take a bath oftener than once a week."

The kitchen carried a legend all the way around urging vegetables in the diet, long cooking of cereals, and the day's food supply with adequate proportions of the various ingredients was shown in the portable kitchen cabinet.

The dining room, in which two children were eating, was clean and attractive with shining dishes, immaculate linen, fruit on board, and the time schedule for meals.

The living room was fitted up with library table, with books and magazines, sewing basket, basket with pine, and candlestick with candle.

The playground was fitted with games, a hobby horse, a swing, knotted for climbing, a child's table with dishes, and on the left was a garden plot with tools for children to do their own planting.

The whole exhibit was exceptionally well thought out, the equipment adequate and practicable, and the lesson of health well taught throughout.

Editorials

THE FIRST city laboratories in the United States were established at Providence in 1888 and at Ann Arbor in 1889; but it was the creation of the laboratory of the New York City

Health Department in 1892 which furnished the main impetus to the development of public health laboratory service upon this continent.

The Public Health Laboratory

Under the inspiration of the late Dr. Biggs, and with the aid of E. K. Dunham and W. H. Park the new methods of diagnosing diphtheria and tuberculosis were introduced at New York and with so much success that the laboratory over which Dr. Park still presides now employs a staff of over two hundred and makes over 150,000 diagnostic examinations for diphtheria alone in the course of a year.

The recent report of the Committee on Health Practice of the American Public Health Association shows that every one of the eighty-three large city health departments of the United States has laboratory facilities at its disposal and that in forty-three cities full time directors of laboratory service are employed at salaries ranging from \$1,500 to \$6,500. In a group of sixty-four cities, for which full data are available an average of eighty-five examinations were performed per thousand persons in the population, at a cost of four cents per capita.¹

A most encouraging feature in the development of public health laboratory service in America has been the emphasis placed on research. The Massachusetts and New York State laboratories and the New York City laboratories, as outstanding examples, produce a volume and quality of research dealing with fundamental problems which compares favorably with the output of the best University departments; and an article in the present issue of THE NATION'S HEALTH² shows how general is this tendency and how fruitful in results.

The laboratory exerts a subtle and far-reaching influence on all the activities of the health department. The work of the sanitary inspector and the nurse in the field and of the physician in his clinic is constantly checked up at one point or an-

other by the rigorous methods of laboratory research, which, with the equally exacting work of the statistician, furnish the controlling force behind the whole health program. In accord with findings of bacteriology and vital statistics our whole campaign must be directed; and its successes in the future, as in the past, will depend upon the extent to which these two basic sciences are fostered and developed.

WHILE one can hardly question that the Schick test has been useful in convincing parents of the need of prophylaxis in those of their children who show positive reactions there is considerable doubt as to

Schick Test or Toxin Antitoxin

whether we have not laid too much stress upon the test and too little upon active immunization. For after all the test will not prevent diphtheria and the results show that in many instances it has merely served to gratify the curiosity of parents. It is no uncommon experience among those doing this work to have parents consent to the test but refuse immunization for positively reacting children.

Granting that the test does induce some parents to consent to active immunization, its effect upon physicians can hardly be anything but a deterrent. Most of the literature extant gives the impression that the Schick test is a necessary preliminary to the use of toxin-antitoxin. The minutiae of the test are recounted, the necessity of accuracy at every stage is insisted upon—the dilution, the intradermal injection, the control injection, the readings of the true, the false, and the combined reactions are described at length, while the simple undramatic but really essential thing is lost to sight amid this maze of technical detail.

Few physicians reading this material are inspired to promote the use of toxin-antitoxin in their private practice and many physicians engaged in health and school work are discouraged from its use by the belief that a preliminary Schick test is necessary. While a preliminary test may be advantageous among children of the higher grades whenever school immunization is to be done, or even in the lower grades of metropolitan schools or those in which diphtheria has been prevalent, or among children from the tenements, or those in institutions, it is not improbable that elsewhere preliminary Schick testing or even mention of it retards rather than accelerates the prevention of diphtheria.

From 50 to 60 per cent of diphtheria deaths oc-

cur among children under five years of age and an additional 25 per cent occur between five and nine. More than half the cases also occur in these two age groups. Children of these ages seldom suffer unpleasant reactions from toxinantitoxin and, except among the classes mentioned above, from 75 to 95 per cent of them react positively to the Schick test in any event. For every one hundred children tested and immunized there must be given from 425 to 485 injections as against but 300 if immunization alone is employed. The latter is simpler, safe and of universal applicability. If the children in the lower age groups can be immunized we can well afford to neglect temporarily those in the higher ones. The death rate in the latter is low, severe reactions from the toxin antitoxin are much more apt to occur, which deter the parents from permitting the immunization of younger children. If we keep tearing at the roots the top will die in any case.

AT LEAST one-eighth of the population of the United States are driving motor cars. Theoretically, each of these drivers is licensed by some legal body. Thirteen million automobiles

A New Public Health Field

are traversing our roads and, where the population is most congested, are passing through streets crowded with human beings. In the city of Chicago alone, more than 300,000 persons are driving what are practically gasoline locomotives, machines of such power and speed as to render them grave health hazards unless they are controlled with accuracy, judgment and a keen sense of responsibility. Even when driven with great prudence, they are potentially dangerous because even the most skillful and careful driver is not always safe from the irresponsible pedestrian. Thus, through reckless driving and careless walking, the death-toll is increasing daily in spite of greatly improved traffic regulation and more rigorous punishment of those drivers whose machines are killing and maiming human beings.

If each day as many people in the United States died from bubonic plague as are killed by automobiles, the entire profession of public health would be stirred to righteous combat with the pestilence. Is it not the duty of the health guardians of the general public to attack any condition which endangers the life and efficiency of man? Is not the prevention of death by automobiles as properly a health department function as the prevention of death from infection? It would seem that it is.

The law can do its part in punishing infractors of the traffic regulations; the press may indoctrinate prudence in both driver and pedestrian; it is the duty of the health officials to prevent the epileptic, the deaf, and the moron from sitting at the steering wheel. No person with a serious heart lesion or a very high blood pressure should be given a driver's license, any more than should the drug addict, the chronic alcoholic, or the individual whose equilibration and coordination are not normal. It is just as important that the automobile driver have safe visual and color sense as it is that the locomotive engineer shall be physically and mentally at par with his responsibilities. A railway company which did not enforce physical, mental and moral factors of safety in selecting its engine drivers would be criminally negligent. In neglecting these simple but important factors of safety with respect to automobile drivers is not the general public guilty of contributory negligence? In other words, would not the medical examination of applicants for automobile driver's licenses and the periodic re-examination of all holders of such licenses bring about a certain reduction in the automobile death rate?

An automobile is an instrument of high power and great precision which none but the physically and mentally safe should be permitted to use, yet men with one arm or one leg or one eye receive licenses and the daily record of automobile accidents set forth in the public prints leads to the belief that many drivers are mentally defective. The primary idea of requiring a license is revenue production to which that of public protection is entirely secondary. The aim should be to license only those who are fit to be entrusted with a machine whose death dealing potentialities are so great.

Some of the larger and more progressive taxicab companies require the successful passing of a medical examination as a preliminary to employment. Is it not a public health function of the community, to impose similar restrictions upon every person who is to drive any motor vehicle?

The production of passenger cars and automobile trucks is increasing at the rate of about 40 per cent per annum. It is reasonable to suppose that the number of drivers is increasing at about the same rate. It seems that here is offered a proper field of health endeavor. To be sure, the medical examination of chauffeurs will not be a panacea against the wave of slaughter by automobiles; it will not be "fool-proof"; it will be a

fairly coarse sieve but it will discourage the person who knows he is not physically fit from applying for a driver's license and it will be the means of removing from the driver's seat, a good many people who are physically, mentally and emotionally irresponsible and who consequently menace human health when entrusted with the operation of motor vehicles.

A VALUABLE recent study on venereal diseases in Czecho-Slovakia¹ indicates that the new cases treated by the physicians of that country for venereal diseases in a year amount to about

Burden of Venereal Diseases

0.6 per cent of the total population, somewhat less than one-third being cases of syphilis. The estimate is based on a questionnaire addressed to individual physicians

and by comparison with the results of the American draft examination, the figures seem to be very low; but the attempt to obtain some real measure of the prevalence of gonorrhea and syphilis is a highly creditable one. It seems probable that the soundest basis for an approximate estimate of the prevalence of venereal disease is to be found in the results of our own draft examination as applied to the second million drafted men. These findings indicated that about 1.05 per cent of the new recruits were suffering from syphilis and 4.62 per cent from other venereal diseases at the time of examination.

We may assume on the basis of these draft studies that at a given moment about one per cent of the young male population is infected with syphilis and nearly five per cent with gonorrhea. We know from numerous series of Wassermann tests conducted on various miscellaneous groups that the total proportion of males affected with syphilis at one time or another rises to between five and ten per cent, five times the result obtained by medical examination at a given moment. We have no simple test for past or latent infection with the *Gonococcus*; but the question naturally arises whether a similar ratio between active disease incidence at a given moment and past infections may not be postulated for the two diseases. We see no very valid reason why such a relation should not exist in view of the ease with which gonorrhea assumes a latent form. If the assumption be a valid one, that is, the assumption that past latent infection in the case of gonorrhea is five times as common as active disease at a given moment, we arrive at the startling conclusion that

1. See review on page 789 of the November, 1922, NATION'S HEALTH.

1. See review on page 789, November NATION'S HEALTH.

at least twenty-five per cent of the male population at one time or another becomes infected with venereal disease. The rates reported by Dr. Pelc in Czechoslovakia were about one-fourth as high for women as for men.

Such conclusions as these must necessarily be very tentative and we invite further discussion of the subject in the columns of *THE NATION'S HEALTH*. It seems time, however, that we should begin to attempt a serious evaluation of the extent of the burden imposed upon society by these communicable and preventable diseases.

THE most striking characteristic of the modern public health movement is the gradual replacement of environmental sanitation by personal hygiene as our central objective. It is particularly interesting to

see how this general tendency has worked itself out in the special field of bathing-pool supervision.

For years past we have been striving to maintain the purity of the water in bathing pools by filtration and chlorination; and this effort is a sound and desirable one. The argument as to the need for such protective measures has been largely based on the evidence of various medical authorities to the effect that infections of the ears and of the nose and throat are commonly noted after bathing in such pools. That such a correlation is in many instances reasonably definite we may perhaps grant; and naturally enough it was at first assumed that the increase in such disorders was directly due to bacterial infection transmitted from one bather to another.

Now comes a new suggestion, that the cases of disease developing after the use of a bathing pool may in many instances be due, not to new infection, but to the lighting up of latent or potential infections already present as a result of the lowering of vitality following undue exposure to the chill of the water. The exact relative weight of various factors remains for the future to determine. We shall do well to keep the water of bathing pools free from pollution as heretofore. On the other hand, the experience already obtained as to the value of direct protection of the ears by special caps or oiled plugs and, above all, as to the control of subsequent illness which can be obtained by limiting the time for which a given individual may remain in the water, makes it clear that in this field of public health as in others personal hygiene is quite as important as environmental sanitation.

WORKMEN'S compensation laws in the United States date from 1911. The original acts have been frequently modified, usually in order to increase the benefits accruing to the workmen.

Medical Compensation Problems

The medical profession figures prominently in the laws and their medical aspect is an important one. The National Industrial Conference

Board has recently published a report which discusses this question at length. One of the most striking omissions in many states is the failure to provide any medical advisor to the industrial accident board or medical member on the board. Of the forty-two states in which Workmen's Compensation acts are in force "fifteen states have a physician attached to the industrial board or commission in the capacity of medical director or medical advisor."¹

One of the most important functions of the industrial accident board or commission in cases of accident is to decide disputes between employee and insurer. These disputes deal almost entirely with questions involving the severity of the accident and the actual period of disability. Medical testimony is always submitted in these cases by both sides and the decision frequently requires a careful weighing of the medical evidence thus presented. It is obvious that only a physician, and one of broad experience, is able to evaluate and assign the proper weight to evidence of this type, and that the commission or commissioner before whom the case is tried, in many cases cannot correctly judge the medical evidence presented. It would seem reasonable that at every hearing before an industrial accident board or commissioner a physician should sit with the board or commissioner, whose business it would be to follow the medical evidence closely and review it in an impartial manner at the end of the hearing. This would eliminate the ridiculous possibilities which are frequently offered by both sides of the controversy. Such a medical advisor should, of course, be carefully selected for his professional judgment and his standing in the community.

Inasmuch as decisions are constantly being handed down by industrial accident boards and commissions which stand as precedents and are followed in later cases, it is of the greatest importance that these decisions should be based upon a thorough understanding of the medical aspects involved.

Serum-Free Solutions of Antibodies

Preparation and Therapeutic Value of Such Preparations in the Treatment of Pneumonia

THE increasing use of animal immune sera in the treatment of various infections of man lends timeliness to any attempt directed toward the refinement and improvement of methods of preparation and administration of such therapeutic agents.

It has long been recognized that the antibodies responsible for the beneficial results of immune serum therapy constituted but an infinitesimal part of the material introduced into the system of the patient. Along with these products it has been necessary to inject large amounts of substances that are either wholly useless or in many instances even produce dangerous reactions. From these statements it follows that antibody solutions free from serum proteins would represent a distinct advance in serum therapy, and this much desired goal has been attained by Dr. F. M. Hüntoon.¹

The object of the investigations which have been so successful was "to determine the possibility of the production of serum-free solutions containing sufficient antibody to permit of their use therapeutically in the treatment of lobar pneumonia." The pneumococcus antibody solutions so prepared are multivalent, giving protection against pneumococcus infections of Types I, II, and III. The preparations "are water-clear solutions containing antibody in approximately the same proportion as serum, but containing only a trace of horse serum, detectable by biologic but not by chemical means, a small amount of bacterial proteins, 0.85 per cent sodium chlorid, and 0.25 per cent sodium bicarbonate." Clinical experimentation has indicated that there are distinct advantages attached to the use of this serum-free antibody solution.

The purification of antibody is a highly technical problem. It may be attempted either by direct or indirect methods. By the direct method is meant the precipitation of the antibody and the redissolving of this precipitate. Such a method must, however, fail to give a pure product for all known method of precipitating the antibody also bring down certain

other serum constituents which it is not possible to separate from the antibody. Hence purification of antibody by the direct method is but partial.

Indirect methods of purification may be either by direct adsorption, indirect adsorption, or absorption, and depend on the use of some substance with which the antibody combines. After this combination has been separated from the major portion of the other serum constituents the antibody is removed from its attachment. Hüntoon's serum-free antibody solutions are prepared by this latter, the indirect method.

A true reversal of the antigen-antibody reaction has never been demonstrated for it has never been shown that all of the antibody was recovered. It is, however, possible to secure a partial dissociation of the antigen-antibody combination and by this method Hüntoon has secured the pneumococcus antibody solution already described. The amount of antibody remaining attached to the antigen after such dissociation is always somewhat more than the minimal sensitizing dose. From this dissociation of the antibody in excess from its combination with antigen arises the assumption that there is a graduated variability in the firmness of the union between these two substances and that those antibodies less firmly attached are the first to be dissociated.

Briefly the preparation of the antibody solution is as follows: At regular intervals horses are injected with emulsions of Types I, II, and III pneumococci. After a number of such injections the horses' serum is found to contain protective antibodies. It is easy to obtain in this manner a serum that will protect mice against one million or more lethal doses of Type I. To obtain as high a protective power against Type II is much more difficult and only rarely can a serum be produced that protects against more than 100,000 fatal doses of Type III.

An equal volume of a heavy emulsion of living pneumococci of Types I, II, and III is added to the immune serum and the mixture maintained at 37° C. for one hour or at 20° C. for twelve hours. During this period the antibody combines with the antigen. Following this reaction period the mixture is centrifuged; throwing down

the pneumococci and the attached antibody. Washing with salt solution rid's this sediment of horse serum.

At this stage in the process of preparation the intermediate product consists of a combination of antibody and antigen having only traces of horse serum remaining. After this sediment is emulsified in salt solution containing 0.25 per cent of sodium bicarbonate the temperature is raised to 55 degrees C. and there maintained for thirty to sixty minutes. In the presence of this salt solution and at this temperature the antigen-antibody reaction undergoes partial reversal and much of the antibody separates from the antigen (pneumococci). Centrifuging this mixture throws down the pneumococci to which part of the antibody is still combined, but the supernatant liquid contains a large amount of antibody. This liquid is removed and chilled, then recentrifuged and filtered through a filter candle. This aqueous solution of antibody contains but a small amount of bacterial proteins, 0.85 per cent sodium chlorid and 0.25 per cent sodium bicarbonate. The nitrogen content per cubic centimeter, is but 0.035 mg. The fact that the antibody content of this solution is approximately equal to the immune serum from which it was prepared is shown by the fact that many lots of the product are able to protect mice against as many fatal doses of pneumococci, Types I, II, and III, as was the original serum.

"The preparation is therefore a practically serum-free, aqueous solution of specific pneumococcus antibodies. It contains protective substances against pneumococcus Types I, II, and III equal in amount to potent polyvalent antipneumococcus serum, yet is almost entirely free from the proteins of horse serum. It also contains in addition to antibody, a small amount of pneumococcus protein which may conceivably act in the capacity of a vaccine and thereby induce a certain amount of active immunity."

Clinical experiments with this type of antibody solution have included more than six hundred cases. In a series of 114 cases treated by Dr. Lewis A. Conner at the New York Hospital which included pneumococcus pneumonias and those caused by

M. Hüntoon and S. Etris. (c) The Chemical Nature of Antibody, F. M. Hüntoon, P. Masucci, and E. Hannum.

other organisms, the total mortality was 14.6 per cent or 8 per cent below the lowest previous record in the hospital and 16 per cent below the usual rate.

Dr. Russell L. Cecil and Dr. Nils P. Larsen² have also used this product. In six wards all cases of lobar pneumonia were treated with the antibody solution. Six other wards were used for a control. Treatment was started immediately following diagnosis. In the majority of cases administration was intravenous. Reactions following the injections are rather unusual. "From twenty to forty minutes after the injection, the patient begins to shiver and is soon in the midst of a hard chill. The cyanosis and dyspnea becomes more marked, and the patient often shows extreme anxiety. The chill may last from fifteen to twenty minutes. At its conclusion the patient complains of fever, and the temperature may have risen to 106 F. or even to 108 or 109. In rare cases the temperature may rise to 110. In one case the rectal temperature was too high to be recorded on the thermometer. When the thermometer was removed, the bulb was missing, and a careful reading of the mercury column recorded 113.10. The patient was wildly delirious during this period of hyperpyrexia, but ice packs were followed by a rapid drop, and on the next morning he showed a normal temperature and made an uncomplicated recovery." Later study of subcutaneous administration shows that by this procedure the severe and uncomfortable reactions are entirely avoided.

The following table, prepared by Cecil, shows the death rates in the treated and control series.

Cases Treated with Antibody			(Control Cases)			
Pn.	Type	Deaths	Pct.	Cases	Deaths	Pct.
Pn. I..	157	21	13.4	175	41	23.4
Pn. II..	78	22	28.2	76	31	40.7
Pn. III..	57	20	35.0	60	24	40.0
Pn. IV..	109	17	15.6	137	31	22.8
Total..	401	80	19.9	448	127	28.3

From this table it is seen that the antibody solution gives the most striking effect in cases of pneumococcus

Type I pneumonia, while there is a noticeable but less marked reduction in the fatality rates for Types II and III.³ The marked improvement in the fatality of Type IV cases is rather surprising since the antibody solution is not sup-

Pasteur and his Grandson. From a photograph presented by the grandson, Pasteur Vallery-Radot, to Dr. M. J. Rosenau.

PASTEUR, who this year has been chosen as the greatest Frenchman, is everywhere hailed as the patron saint of preventive medicine. Not by dint of mere discovery through observational method, but chiefly through his power to visualize the ultimate application of laboratory findings were the foundations laid by Pasteur for present practice in active immunization. The story is old of his work on anthrax, of his attenuated cultures of chicken cholera making hens refractory or immune to this disease, and of the first preventive treatment of rabies in a human on the Alsatian boy, Joseph Meister, but the dramatic salvage of human life through the principles so evolved is an everyday occurrence in health work.

Chemists must regard Pasteur as having shown the open road to truth through experimental evidence. With the discovery of bacterial habit, bacteria themselves were turned to beneficent uses and specific prevention of diseases ushered in the era of preventive medicine.

posed to offer any protection against this type of infection. There is considerable evidence that Type IV is composed of aberrant forms of Types I, II, and III. If this hypothesis is correct the beneficial effect on the antibody solution on Type IV pneumonias can be explained.

The following table,⁴ also from Cecil's work, shows the more marked effect of antibody solution when it is

administered on or before the third day of the disease. The control shows the deaths among cases admitted to the control wards on or before the third day of the disease.

From this it is seen that the mortality from all four types was reduced one-half when treatment was instituted in the first days of the disease.

The dose used was from 50 to 100 c.c., given once or twice a day, and occasionally three times.

It must be concluded from these results that this antibody solution is of considerable value in the treatment of pneumococcus pneumonias. There is no danger of anaphylactic shock and it now appears that subcutaneous injection will avoid the chill and fever that accompanies intravenous administration.

In the preparation of the antibody solution Huttoon has investigated the nature of the antigen-antibody reaction; the possibility of reversing the reaction; the technic of recovering antibody from sensitized antigens; and the chemical nature of the antibody, technical problems of immunology that have long needed study.

He has recovered a large part of the antibody from sensitized antigens and studied the agents and factors that influence the degree of such dissociation. As a result there is now available a serum-free solution of antibodies that are very effective

in the treatment of lobar pneumonia. From his study of the chemistry of the problem Huttoon concludes that antibodies do not belong to that group of proteins usually considered under the head of serum proteins." Even such a negative conclusion as this is of value in limiting the field of investigation in relation to the nature and action of antibodies.

The Toledo Municipal Hospital Clinic

MORE properly than other services does the control of venereal disease come within the province of municipal health machinery. The Toledo Municipal Hospital Clinic, is a notable example of a health service

facilities designed at the beginning as an emergency organization for venereal control during the war, have since been expanded to permit the care of communicable diseases other than venereal, but the venereal control

room are grouped smaller rooms used as treatment room and wards for the segregation of the more acutely ill patients or the younger patients. Future plans involve an expansion that will permit the detention of all police charges in the hospital. The remodeled hospital building will soon be ready for occupancy.

The channels through which patients are received are many and various. In handling prostitutes the clinic cooperates with the police department and with the sanitary police of the department of health. These cases are confined for the full period of their infectiousness. Other cases reach the clinic by reference from hospitals where accommodation is not available. Such charitable organizations are fruitful sources and the district nurses, the tuberculosis dispensaries, and home for girls.

Public school nurses and outside physicians refer indigent patients to the clinic. But by far the greater number of the patients are voluntary applicants, especially the male patients. Those who are able to pay outside physicians are directed to proper outside channels for treatment.

The clinic is open every day except Sunday. On Wednesday the entire staff is devoted to the administration of intravenous treatments, on which day no new admissions are received. In every case, from whatever source,

Venereal Clinic, Municipal Hospital, Toledo, O. Cooperation and collaboration with the private physician are maintained at all times.

operating primarily on the basis of a police power making communicable diseases subject to report and quarantine. The activity is under the control of the welfare department and is supported by the budget of that department. It bears no relation to the state health department or the United States Public Health Service, other than to render monthly reports to those bodies. The policies of the clinic are entirely controlled by the city government.

The clinic is in charge of a director, who is responsible for the three departments: (1) Urological, (2) nursing, and (3) clerical. The urological staff consists of the director, who is chief urologist, consultant, and adviser in all cases; the assistant director, who has charge of the female service, and two assistants urologists. The nursing staff consists of the head nurse, who is also superintendent of the hospital, eight full time, graduate nurses, and two male nurses. The clerical force includes a full time social worker, a stenographer, and a statistical clerk.

Describing the scope of the work, Dr. Earl W. Hufer, in the *American Journal of Syphilis*, states that its

clinic is still the *raison d'être* for its existence. The ground floor is occupied by the executive offices, the clinic for men, a small instrument room, and a small and at present inadequate operating room. There are two large, widely separated, wards on this floor, one for men and one for women. Thirty-eight beds are available in the hospital, and the overflow on the female side is accommodated in the detention home. The second floor is devoted to the clinic for women. Around the large waiting

Shows arrangement and fittings of small laboratory in male clinic.

Endoscopy and cystoscopy room.

a complete social history is developed by the social worker to supplement the clinical history. The clinical record card combines simplicity with sufficient detail and the daily recording system affords ample data for the required monthly reports to the state department of health.

The expansion of the influence of the clinic is indicated by the increase in the number of ambulatory patients treated from 7,653 over the period from July 7, 1918 to August 15, 1919, to 27,110 covering the period from January 1, 1921 to December 31, 1921. Interned patients treated increased for

similar periods from 201 to 949. A very tangible evidence of the actual results being accomplished is shown by the annual report which says: "We have taken care of 621 police cases—only 31 per cent of them were infected—while in 1919, out of fifty-two girls taken in one raid, only one was not infected." The statements is added that prostitutes in Toledo are the least source of danger under current management. The greatest source of danger lies in the unknown, who do not come under the observation of the police. Early detection is the price of safety.

Hope for Heart Cripples

THE Association for the Prevention and Relief of Heart Disease has recently published its second report covering the period from January, 1921 to December, 1922.

In order to show the magnitude of the problem against which the efforts of the association are directed, figures are quoted showing that the rejections on account of heart disease among men of military age during the war was 42.3 per 1,000; this figure including those rejected by the local boards and in addition those rejected on a second examination at an army camp. Records of rejections by a large insurance company were 24.4 per 1,000 in spite of the fact that persons with the more obvious forms of heart defect are not apt to apply for insurance. In addition it must be remembered that probably some good risks with but a slight defect were accepted. The city health department of New York has found that 16 per 1,000 of the school children have heart defects.

The association has organized forty-three special clinics in the hospitals of

New York City, devoted to the exclusive care of those suffering from heart disease, and has established fifteen segregated classes for children in cooperation with the Board of Education, the Public Education association, and seven cardiac clinics.

With the help of the educational authorities and the Children's Aid Society has organized and supervises a trade school for cardiac girls. It has obtained the cooperation of the fresh air organization in obtaining summer outings for cardiacs; and secures the admission of cardiacs to convalescent institutions.

It has conducted studies of children refused working papers on account of heart defects; of suitable occupations for persons handicapped with heart disease; and of the facilities available for the care of chronic heart disease in New York City.

The central office of the association serves to coordinate all medical and social organization interested in the problems of cardiacs. It prints and distributes educational literature on all phases of the heart problem and has given assistance and advice in the formation of associations and clinics for the care of heart patients in 26 other cities on the continent. A movement has been started recently for the formation of a national group to organize the work on a country-wide basis.

Laws substantially conforming to the uniform illegitimacy act adopted by the National Conference of Commissioners on Uniform State Laws, have been passed in Nevada, New Mexico, North Dakota and South Dakota.

Illinois has provided for a survey by the department of public welfare of the numbers, location, and types of children of school age specially handicapped physically, psychologically, or socially.

Iowa, Minnesota, and Ohio have passed laws relating to physical education in the public schools.

Exercise is not denied the little heart cripples who are under special management in the Mineola Home, New York, but suitable adaptations are made and the children encouraged to maintain what is, for them, normal activity.

Society Needs the Centenarian Groups

THE picture of The Centenarian Club of Los Angeles, Calif., which is shown on this page, is only a part of the story of this young-old group who are all old in years, but who without exception have retained their outside interests and have maintained a relatively wide range of activities. And the picture does not tell the whole story, for four persons present at the party were out of focus and so members of the club who are missing in the photograph include Dr. H. L. Canfield, age 95; Samuel Hedges, 94; Mrs. Maria Bailey, 95; and Mrs. S. H. Bliss, 91. The average age of the whole club is but slightly under ninety-four years and among them are men who do ten-mile sprints, women who do mountain climbing, and do their own housework. The men are all socially active, some of them in a business way as well.

The purpose of the club is that of friendliness and pure fun. Birthday parties are the rule, picnic dinners are frequent, and hikes are not uncommon, for a number of the members. The club ideally provides those interests and contacts the lack of which, according to G. Stanley Hall, account chiefly for the unhappiness of many persons in the older groups and especially for the peculiar detachment which to so great a degree serves to convert old age into a period of uselessness. "We suffer chiefly from unripeness," he says. "The human stock is not maturing as it should. Life is so complicated that the years of apprenticeship are ever longer and harder so that we are exhausted ere we become master workmen in our craft, and the rapid age turnover this

involves robs us of too many of the choicest fruits of experience."

Naturally, as a genetic psychologist, Hall in his study of "Senescence" discusses rather fully the mental hygiene of old age. Age itself may be regarded as the result of attitudes. We have the senescent period of earned repose, coming normally and as a welcome respite from pressures the physical organism is no longer resilient enough to welcome; but this is quite different from the enforced re-

range of activities. Psychoanalysts do not bother to study and treat persons past middle age, even though certain guidance during the climacteric of both sexes might well serve to teach the aging and aged to hold on to those very satisfying compensations that come after the painful renunciations of youthful pursuits.

The account Hall gives of his own readjustment to advance of years is very interesting. His retirement, a deliberate self-effacement after a life-

time of intensive and productive effort, brought him summarily face to face with a painful cessation of practically all his habitual functions. A hygienic survey of his physical assets brought to him the realization that physicians really know very little of old age, few having specialized in its distinctive needs. Thus the older a man is, the more he must rely upon his own hygienic

A picture of the Centenarian Club of Los Angeles, Calif., taken at the home of Silas Judd on his ninety-seventh birthday. The members are (first row seated, left to right): Mrs. Mary Chalker, age 91; Silas Judd, 97; Mrs. G. R. Pease, 95; Mrs. J. F. Howard, 97; Mrs. J. P. Vandergrift, 97. Second row: Sam Coles, 100; Mrs. E. M. Fletcher, 82; J. R. Alter, 82. Standing: General J. S. Wilcox, 99; M. H. Merriman, 94; J. M. Green, 91; Galusha M. Cole, 96; Joseph Sigle, 95.

tirements in industry at a period when men should be able to occupy themselves to the time limit of their productive capacity. The social attitude, which scorns the tempered judgment of matured minds, contributes toward the production of an untimely old age; but even that is not so deadly as such a narrowing of interests and such mental inflexibility on the part of the aged themselves as require an undue degree of tolerant consideration on the part of the younger generation.

Unfortunately, the mental hygiene of old age has been greatly neglected by the psychologists. There is not even a standard by which an intelligent man can measure himself to learn whether he is achieving safe and sane adjustments to his narrowing

sagacity for health and long life. The lives of the centenarians Hall studied convinced him that they owe their long life more to their own insight than to medical care and, he says, there seems to be far greater individual difference of needs than medicine has yet recognized.

Thus the aged are alone with a new kind of solitude and must pursue the rest of life in a more or less individual research as to how to keep well and at the top of condition. The specialists Hall consulted agreed that the older person must eat moderately, slowly, and oftener, and less at a time; must sleep regularly; cultivate the open air; exercise till fatigue comes and then promptly stop; be cheerful; avoid "nerves," worry, and

all excesses. But here agreement stops. One suggests change; one says Fletcherize; one says limit the diet; another says eat what you want; one suggests glandular extracts; another recommends youth-producing exercises.

The habit of living grows strong with years, and reasonable adjustments make the habit harder and harder to break. Now that the span of human life is lengthening, early death is not so much to be countered as the type of civilization that disregards the immense possibilities of productiveness on the part of highly trained persons whose necessary break with youth only serves to clear the deck for single track thinking and effective effort. The dangers of old age are a problem of the aged themselves; but the deliberate loss of ripe judgment, of mature activity, and of disinterested service—if disinterestedness is ever to be counted upon in service—are problems of a social nature open to serious consideration on the part of everyone.

On the mental hygiene of old age, the achievement of a philosophic acceptance of age and its inhibitions, Hall says that to learn that we are really old is a long, complex, and painful experience. Regarding the mental attitude toward age he addressed his inquiry toward two widely separated groups. The personal equation is great. All of the replies he received from persons in homes for the aged revealed pathos and pessimism galore. Disciplined tranquility and serenity were rare. Another list, all Americans, and all drawn from successful, even prominent groups, tend to be complacent and seem to look upon life as a whole as a triumph of virtue and have usually evolved a highly satisfactory basis of living. They have become more intensely individual and have managed to invest the same old self with a new set of attractive attributes and, while it is really impossible for youth fully to sympathize with age, or age with youth, enough of common ground is maintained for the social graces that are necessary to youth and age alike.

Connecticut Authorities Question Medical Degrees

Two members of the State Examining Board of the Connecticut Electric Association have been found to hold diplomas from the Kansas City College of Medicine and Surgery, the "diploma mill" which is accused of selling diplomas at from one hundred to five hundred dollars each and

"coaching" such graduates so that perfect and identical answers were made to examination questions prescribed in Connecticut. It is held that about two hundred "doctors" have been marketed in Connecticut.

Governor Templeton, acting quickly in the matter, has conferred with Dr. Stanley Osborn, head of the State Health Department, has commended the activities in this connection by State's Attorney Alcorn and is likely to request an extraordinary grand jury and a specially registered assistant to press conspiracy and perjury charges.

The Coal Tar Chemical Industry

Studies recently made of the technical group employed in the manufacture of coal tar products have several interesting aspects.

Of the 209 firms engaged in the industry, reports from 177 have been tabulated. About 23 per cent of the total of 1,757 men reported only 401 chemically and technically trained men received a wage of \$75 or more per week. This industry carries a larger proportion of technically trained men than any other manufacturing industry in the United States, and the total number of firms engaged in it has increased from 7 in 1914 to 209 in 1922.

Patent Remedies of Fearsome Compounds

The *Chemical Age* mentions a patent for a hair tonic which is composed of the oil of onions, cabbage and parsley, mixed with borax, sulphur, sugar of lead, ammonia, salt, alcohol, and bay rum. Still another patent for hair tonic about the time of the eighteenth amendment calls for a mixture of French vintages and other supposedly palatable ingredients. No wonder the nation is growing bald.

French Dentists Disagree

There is dissension among French dentists. Far too few in number to take care of the dental needs of the people, dentists have found their field usurped by empirics or even out and out charlatans, a condition which an attempt to control under the law of 1892 further complicated; for the requirement that "dentistry shall be practiced only by persons possessing a degree of doctor of medicine or a diploma as dental surgeon" introduced into the ranks of dentists a considerable proportion of physicians who oppose the separation of dental science

from medical and are arguing for a degree of "doctor of stomatologic medicine."

The desire of the dentists to authorize a "degree of doctor of dental surgery," to be followed by another degree of "doctorate of odontology" is opposed by the medical profession chiefly because they fear a flood of special doctorates that would eventually undermine the degree of doctor of medicine.

The increased interest in France in the care of the teeth is attributed by the Paris correspondent of the American Medical Association to the excellent mouth condition of American soldiers, and it is held that the dental care prescribed in the new military regulations in France will have the universal result of a more rational care of the teeth and will call for the reorganization of professional requirements to meet the new demand.

Lepers Lose Infirmary Building

Costs of construction having increased 20 per cent in Louisiana since last spring, when Congress provided \$650,000 for the construction of additional buildings at Carville, La., the building program is curtailed by eliminating the infirmary needed for treatment of the blind and the crippled. The seventeen cottages housing twelve lepers each, the dining room and kitchen unit, the necessary power plants, and water and sewage disposal units are being built.

Insurance Records in Employee Policy

A new record in the size of a single insurance policy was set when the Southern Pacific Railroad company took out a \$100,000,000 contract covering the ninety thousand employees of that railroad. The policy automatically insures the lives of all employees who have been with the road six months. The expense of this initial policy on the life of each employee is borne exclusively by the company, but the employee has the privilege of purchasing additional insurance up to a maximum of \$3,500 for those receiving a monthly wage of two hundred dollars or more, the additional insurance to be paid for jointly by the employee and the company under a contributory plan.

Professor George Chandler Whipple, who has for nine years represented the field of sanitary engineering on the Public Health Council of Massachusetts, has resigned this connection.

First Aid In Asphyxiation*

A handkerchief is not a gas mask. This has cost many lives.

RULES for first aid and resuscitation in gas asphyxiation issued by the commission which has just completed its study of the subject under the auspices of the American Gas Association are just issued in the form of an illustrated booklet. The subject is concisely treated under the headings: (1) What carbon monoxid does. (2) Protect yourself. (3) Get the man out of gas. (4) Watch an unconscious man every minute. (5) When to give artificial respiration and when to give inhalation. (6) Artificial respiration by the prone pressure method. (7) How to take care of the patient. (8) General directions.

The reason that automobile exhaust gas, the gases from coal heating furnaces, the smoke from fires, producer gas, coke oven gas, blast furnace gas, carburetted water gas, coal gas and other manufactured gases are poisonous if actually breathed is that they all contain carbon monoxid. When carbon monoxid is breathed it combines with the blood, cuts off the oxygen supply, and the gas victim becomes asphyxiated just as if he were gradually being choked to death. As low as one-tenth of 1 per cent of carbon monoxid, or even less, will kill a

man in time; 1 per cent will kill in a few minutes.

If the patient does not die in the gas, but is removed to fresh air, the carbon monoxid leaves the blood in a few hours. The quicker it is breathed out of the blood, the better the chances of recovery. If the asphyxiation has not been too long or severe, and first aid treatment has been prompt and correct, recovery is complete.

The first word of warning from the Commission is, "Protect yourself." If the rescuer must go into gas or smoke, a mask and air hose or a gas mask with canister is to be worn. Particular emphasis is made that the mask must be especially made to stop carbon monoxid. The patient is to be moved immediately to a comfortably warm atmosphere that is free from gas, and artificial respiration by the

Air hose and mask, the best and safest apparatus when it can be used. A lifeline is essential under the conditions illustrated.

prone pressure method is to be resorted to at once if the patient is not breathing or if his breathing stops. A delay of a minute in such a case may be fatal. If the patient is breathing, he is to be laid in the first position for prone pressure resuscitation.

Artificial respiration is to be undertaken and pursued thoroughly even if the patient appears dead. As soon as the patient is clear of the gas quickly feel with your finger in his mouth and throat and remove any foreign body (tobacco, false teeth, etc.). If the mouth is tight shut, pay no more attention to it until later. Do not stop to loosen the patient's clothing, but immediately begin actual resuscitation. Every moment of delay is serious. Proceed as follows:

(1) Lay the patient on his belly,

one arm extended directly overhead, the other bent at elbow and with face to one side, resting on the hand or forearm, so that the nose and mouth are free for breathing.

(2) Kneel, straddling the patient's hips with knees just below the patient's hip bones or opening of pants pockets. Place the palms of your hands on the small of the back with the fingers over the ribs, the little finger just touching the lowest rib, the thumb alongside of the fingers; the tips of the fingers just out of sight.

(3) While counting one, two, and with arms held straight, swing forward slowly so that the weight of your body is gradually, but not violently, brought to bear upon the patient. This act should take from two to three seconds.

(4) While counting three, swing backward so as to remove the pressure.

(5) While counting four, five—rest.

(6) Repeat these operations, deliberately swinging forward and backward twelve to fifteen times a minute—a complete respiration in four or five seconds. Keep time with your own breathing.

(7) As soon as this artificial respiration has been started, and while it is being continued, an assistant should loosen any tight clothing about the patient's neck, chest, or waist. Keep the patient warm.

(8) Continue artificial respiration without interruption until natural breathing is restored, if necessary four hours or longer, or until a physician declares rigor mortis, (stiffening of the body) has set in. If natural breathing stops after being restored, use resuscitation again.

Gas mask and canister. Special chemicals are needed in the canister to absorb carbon monoxid.

*From the report of the Commission on Resuscitation from Gas Asphyxiation. Dr. Cecil K. Drinker, Chairman; Drs. Walter B. Cannon, David L. Edsall, Howard W. Haggard, Lawrence J. Henderson, Vandell Henderson, Francis W. Penbody, Royd R. Sayers, and Charles B. Scott, members.

A man who has been even slightly gassed should not be allowed to make any exertion. Keep him lying down. If he must be moved, carry him. The worst thing that can be done is to get him up and walk him around—as is sometimes done. It may injure his heart or even kill him.

When a gassed patient is breathing he should not be given artificial respiration; but he should be placed and kept in position ready for artificial respiration in case he stops breathing. If the patient is not breathing,

artificial respiration by the prone pressure method described is called for at once. This is the best method for artificial respiration. It is better than any method using a mechanical device. If the victim is breathing, an artificial respiration apparatus may injure him. If he is not breathing, he may die while the apparatus is being secured or while it is being put in order for use.

Oxygen inhalation used properly helps to drive the carbon monoxid from the blood. To do any consider-

able good the oxygen must be given during the first two hours after the man is out of the gas. It is recommended by the report that about 5 per cent of carbon monoxid be mixed with the oxygen inhaled as this makes the patient breathe more deeply and thus allows the oxygen to drive the carbon monoxid out of the blood. The report closes with specific directions for the care of the patient and for administering the inhalation treatment.

Interconnection of Water Supplies

INSURANCE rates for a factory or manufacturing plant having a large fire risk are largely governed by the supply of water available for fire protection. Insurance companies properly require that there be installed on large and valuable properties an independent water supply either to duplicate or supplement the public supply, or the insurance rates are accordingly raised.

In attempting to comply with the underwriters requirements at the least expense the owners of factories often find themselves in conflict with the health authorities; particularly when they resort to interconnections of public and polluted private supplies.

Since chlorination and filtration of water and the purification of sewage have become so general in urban districts typhoid fever epidemics have notably decreased. At the same time a larger percentage of the epidemics occurring are attributable to what were once considered the more unusual sources of pollution, particularly cross connections between public and private industrial water supplies.

Thorndike Saville has said, in considering the question of whether or not water for private fire supplies should be permitted under any conditions to be taken from a polluted source: "Protection from conflagration is just as important to the public welfare as is protection from disease, and all public officials should recognize that these two factors are interrelated. Nor is it entirely proper to weigh out the evidence in terms of statistics and probabilities. It may be claimed that the chances of death from disease from interconnection are vastly less than the chances of death from fire without interconnection. The answer *should* be that if absolute separation of public and private sources is reasonable, and will afford

adequate fire protection, then the chance of disease from interconnection of supplies is too great to be taken, no matter how remote it may be.

"This is the only logical standpoint, and is to be set up as an ideal. In practice, we often do not live up to ideals, and frequently our processes

overflow by a connection from the city main. Such tank or standpipe may then be connected to the fire protection system.

"Third. Two independent systems of piping without any connection whatsoever, one being supplied from the city mains and the other from the independent water supply.

"The Ohio State Board of Health has permitted cross connections between public and private water supplies with the use of double check valves, but has withheld approval of this method of procedure."

That dangers attend the use of double check valves is shown by the fact that in Hartford, Conn., since the installation of check valves in 1919, sixty-one instances of leakage through one valve and six instances of simultaneous leaking of both valves have been recorded. If such devices are in use there should be at least bi-weekly inspection tests but it is preferable to prohibit their use and adopt some such system as that shown in the accompanying illustration.

of reasoning are anything but logical."

It seems reasonable to allow the use of a private water supply when it is the most economical method of meeting the underwriters' and insurance requirements and is satisfactory taken, no matter how remote it may be, to the health authorities. The best solution of this problem is by interlocking regulations of the State Insurance Commission and the State Board of Health.

The Ohio State Board of Health has taken the attitude that any interconnection of a polluted private supply with the public water supply is potentially dangerous and that absolute safety can be secured only by the following methods:

"First. Construction of a pump well or reservoir to which the city mains are connected, pumps taking suction from well or reservoir and pumping to an elevated tank for storage and pressure.

"Second. An elevated tank or standpipe supplied at the top and above the

Correspondence Course for Nurses

The second year begins with a full quota of nurses taking the correspondence course in public health organized by the New York State Department of Health for the purpose of qualifying nurses employed in that state by county or municipal authorities who, after January 1, 1924, are required under law to have completed an approved course of public health instruction. The course is conducted by the University and Bellevue Medical College and is limited to 250 nurses.

The new Yale School of Nursing will receive its first student nurses in February, 1924.

Occupational Therapists Convene at Milwaukee

THE members of the Wisconsin Occupational Therapy Association acting as hosts, details were arranged which made for efficiency in the management of one of the most successful sections of the Milwaukee conventions. The program, a souvenir number of the official organ of the Wisconsin association, contained much valuable information about actual work being accomplished so that it was easy to cover the various phases of the work desired by visitors.

The report of the financial committee showed some discrepancy between the recommendations of extended work and its possibility under the present budgets, but organization was effected to secure additional funds to carry out an effective program through securing a full-time, paid assistant secretary. Membership in the organization now numbers 588 and inquiries on standards, installations, materials and methods have developed the need of correlated studies and information bulletins. Inquiries have been tabulated not only from members and hospitals about to establish occupational therapy departments, but from Canada, India, China, Japan, New Zealand, Holland, and Great Britain. The need for workers is so great that it has not been found possible to fix an efficiency limit even as to the number of patients it is possible for one worker to serve. The address of the president, Mr. Thomas Bessell Kidner, dealt in particular with the necessity for developing through organization activities a sane, national leadership.

Mentioning some directions in which such leadership is necessary, Mr. Kidner denounced particularly a strong tendency in many quarters to render the work purely commercial, that is, to produce in treatment by occupation, articles chosen primarily because of its ready sale. Success in occupational therapy is not to be measured by sales made, but by its specific adaptation to the patient involved and to its general effectiveness in restoring the patient's interest and powers. Outward and visible signs of occupational effort are therefore no real criterion of a properly functioning department. The hospitalization of a patient may be definitely shortened by occupational therapy, and this must be the measure of the economic efficiency of the department.

Mention was made of the great therapeutic possibilities in work with handicapped children, a field which has scarcely been touched. Particularly should occupational effort be made possible to cripples confined in their homes which would interest them while it afforded opportunity for vocational training and advice. While this service is equally applicable to adults, the possibilities through this means of developing the personality of the child, of educating him, and of giving him independence and self-respect have not been developed.

An important feature of the first day's session was a report on forms and records representing studies made by a committee headed by Dr.

Horatio M. Pollock of the New York State Hospital Commission.

The value of pre-industrial shops in rehabilitation received emphasis by Dr. Foley, Chicago, who declared that curative results in patients of the Chicago State Hospital are none the less positive because the activities represent useful and gainful occupations. This phase of the subject was further developed by Walter J. Hamilton of Chicago, the well known industrial and vocational counsellor on personnel. His message was that the occupational therapist cannot and should not remain detached from other agencies of rehabilitation outside of the hospital. Federal and state authorities in nearly forty states are now cooperating in the rehabilitation of disabled workers and citizens; the physician, the nurse, the occupational and physiotherapist, the vocational counsellor, social agencies, the official centers of rehabilitation, and employees must coordinate their efforts in order to be effective in this field.

A note of caution was sounded in the address of Major B. E. Hedding, who took for his topic: "Is it Occupational Therapy?" He argued for occupation only on prescription of the physician. Many activities have been undertaken with the tuberculous in the last twenty years, he said, but out of them only a few really serviceable occupations, although occupation must be considered the chief and best treatment.

R. K. Atkinson of the Russell Sage Foundation made an interesting con-

Members and guests of the American Occupational Therapy Association, which met for the second time in conjunction with the American trips of inspection and study of the large

tribution in recounting the mental reorganization that is possible through rhythmic work and music among insane patients. Everywhere improvement in the general mental and nervous condition accompanies the rise of interest and increase of skill in group exercise, folk dances, and similar activities.

Curative work as an integral part of hospital treatment in industrial service as employed by the French and Early institution in Los Angeles was discussed by Mr. C. J. Glasser. He mentioned especially that neurosis, formerly so common with them in back injuries, are under a system of directed occupation entirely lacking.

Immediately at the close of the morning session the members journeyed out to Wauwatosa, where they were the guests of the county authorities at luncheon in the dining hall of Muirdale Sanatorium. During the luncheon three-minute reports were given by members from most of the states. Everywhere progress is being made, as was evidenced by the talks of the speakers. Visits to the occupational therapy department in the Muirdale Sanatorium and to the fine and attractive curative workshop at the County Hospital for Mental Diseases followed. Dr. G. F. Bellis of Muirdale and Dr. Young of the County Hospital formally welcomed the visitors and received their hearty thanks for the excellence and completeness of all the arrangements made for their entertainment and instruction.

Round table discussions filled the rest of the day. Dr. W. R. Dunton, Jr., Sheppard and Enoch Pratt Hospital, Towson, Md., presided over the discussions on work in mental hospitals.

Mrs. Gertrude Sample, chief of the occupational service, U. S. Veterans' Hospital, Oteen, North Carolina, was

chairman of the round table on work in tuberculosis sanatoriums.

Occupational therapy in general hospitals formed the subject of the discussion at a round table presided over by Miss Elsie Hassenstein, director of occupational therapy, Cook County Hospital, Chicago, Ill. Mrs. Grace Pebbles, of the Vocational Society for Shut-ins, Chicago, presided over the group discussions on work for the home-bound.

The officers elected for the year are as follows: president—Mr. Thomas Bessell Kidner, National Tuberculosis Association, New York, N. Y. (re-elected); vice-president—Dr. G. Canby Robinson, Johns Hopkins Medical School, Baltimore, Md. (re-elected); secretary-treasurer—Mrs. Eleanor Clarke Slagle, director of occupational therapy, New York State Hospital Commission, New York, N. Y. (re-elected); Board of Managers—Dr. Philip King Brown, Arequipa Sanatorium, San Francisco, Cal. (re-elected); Dr. B. W. Carr, Chief, division of occupational therapy, United States Veterans' Bureau, Washington, D. C. (re-elected); Mrs. Carl Henry Davis, Wisconsin Occupational Therapy Association, Milwaukee, Wis. (re-elected); Mrs. Elias Michael, Missouri Occupational Therapy Association, St. Louis, Mo. (re-elected); Dr. H. M. Pollock, State Hospital Commission, Albany, N. Y. (re-elected); Dr. Frankwood E. Williams, National Committee for Mental Hygiene, New York, N. Y. (re-elected); Dr. W. R. Dunton, Jr., Sheppard and Enoch Pratt Hospital, Towson, Md.; Mrs. Fred W. Rockwell, member of board of managers, Philadelphia School of Occupational Therapy, Philadelphia, Pa.; Mrs. Frederick Dale Wood, president, Illinois Society of Occupational Therapists, Chicago, Ill.

Hearty thanks were unanimously voted by the members to the Wisconsin

Occupational Therapy Association for the splendid services rendered in making such complete arrangements for the convention, and in particular for the fine souvenir program.

City Manager Government Credited with Dayton Progress

The Dayton, Ohio, Research Association has published a pamphlet on "Ten Years of City Manager Government," which credits to municipal reorganization so effected the following very material advances in health activities:

Greatly extending the city water works and placing the system on a paying basis.

Organizing the health department on modern lines, introducing a staff of five city physicians to serve the indigent sick in their homes and in clinics provided by the city.

Establishing a centralized public health nursing system by combining forces with private health organizations, and placing the whole under the supervision of the health department.

Establishing a complete food and dairy service; requiring pasteurization of all milk sold in the city, and medical examination of all food handlers.

Reducing the infant death rate from 124 per thousand to 67 per thousand.

Moving the city workhouse to a hundred-acre farm. Erecting a new workhouse which is operated by modern correctional methods.

Introducing a parole system which permits workhouse prisoners to work, their earnings being applied to the care of their dependents.

Establishing a free legal aid bureau with an attorney paid by the city.

Working in connection with the Dayton Playgrounds and Garden Association in conducting public playgrounds.

Establishing a crime prevention bureau.

Establishing medical inspection in the schools.

Establishing a central purchasing department which operates a centralized store system.

Establishing a sinking fund on an actuarial basis.

Hospital Association in Milwaukee, October 30 to November 3. Three days were devoted to conference sessions, and one day was given over to exhibits of work accomplished by member associations.

LATE HEALTH DECISIONS IN THE COURTS

BY DOROTHY KETCHAM. UNIVERSITY HOSPITAL, ANN ARBOR, MICH.

THE Supreme Court of Illinois decided recently that where an injured employee after an accident contracted gonorrhea, and the resulting gonorrheal arthritis postponed his recovery for many months, that he could not recover under the Workmen's Compensation Act for any disability caused by the disease "An employee can only recover for a disability that is caused entirely by the accident which he received in his employment, and—the employer is not responsible for any part of a disability that has been occasioned by another independent agency that has intervened after the accident occurred."—*Bunge Bros. Coal Company v. Industrial Commission*, 138 N. E. 189.

THE following situation which was passed upon by the Supreme Court of Pennsylvania recently, shows the type of evidence necessary to prove accident. On the morning of May 3, 1920, Riley, a clerk, complained of pain in his left chest and about three hours later coughed up blood, but continued to work until evening. On return home, and on the advice of his wife, he went to the family doctor and related the symptoms. He stated that while lifting an adding machine that morning "he felt something give way in his left chest." The hemorrhages continued until Riley's death twelve days later. No one saw him lift the adding machine on this day, although he had sometimes done so on former occasions, and while in the office of the plant physician, although complaining of pain, he said nothing about a strain or accident. The referee rejected the claim for lack of proof but the compensation board allowed it. The court of common pleas reversed this decision and returned it for rehearing, where, after additional evidence, the claim was again allowed and again rejected, hence the appeal.

The Court states that while it is not necessary to prove that the injury arose out of the employment, "it was incumbent upon the plaintiff to show her husband died from an action sustained in the course of his employ-

ment." This she sought to do by declarations made to herself and to the doctor over ten hours after the accident, during which time he (Riley) had been working. . . . "There is no ground upon which such declarations are competent as evidence—where the declarations are made under such circumstances as will raise the reasonable presumption that they are spontaneous utterances—and so soon thereafter as to exclude the presumption that they are the result of premeditation and design. . . ." they will be admitted as evidence.

There was no autopsy and apparently no positive evidence to support the findings.—*Riley v. Carnegie Steel Co.*, 119 Atl. 832.

THE Supreme Court of Michigan June 4, 1923, passed upon an award of compensation for neurasthenia caused by accident as a "personal" injury within the meaning of the compensation law.

The plaintiff was injured December 16, 1920, while working in an iron mine, suffering an inguinal hernia, later operated on. He was paid compensation for twenty-two and a half weeks and signed a settlement receipt, but later petitioned for further compensation, which was denied. April 4, 1922, he again petitioned, and, on hearing, an award was fixed to begin September 14, 1921, the date of the former decision. On review by the commission the award was to begin April 4, 1922.

According to the rule, a case cannot be reopened without additional facts as to the physical condition of the employee which may include the fact that the patient is worse than seemed indicated at the time of the original award. It seems that in this case that the plaintiff developed neurasthenia which was present at the last hearing, but which fact was not emphasized. The court states that neurasthenia caused by an accident or attributable to such is a personal injury under the act, and that since the evidence is capable of the inference that the disorder is worse than it was at the time of the former hear-

ing, the opinion of the previous court is upheld and additional award affirmed.—*Harris v. Castile Mining Co.*, 193 U. W. 855.

THE Supreme Court of Pennsylvania recently passed upon the matter of industrial disease and accident. An employee about twenty-one years of age claimed to be wholly incapacitated for work because of a disease of his right hip joint known as ilium osteoarthritis. On July 18, 1921, he entered the employ of the Budd Company as a press helper. An examination at the time by a physician in service of the defendant showed that Balch was in a normal physical condition and above the average. August 10, 1921, while he was lifting the center of a die with others, he sustained a rupture in his right groin. It was contended by him that the present development was the result of the injury, which was denied by the referee. On appeal the board after hearing *de novo* reversed the decision and made an award.

The board found that in the course of his employment this man sprained himself, suffered acute pain, "and at the time was rendered incapable of further work, and in consequence thereof, a hernia developed." This finding was supported and the question of the presence of typhoid raised but not upheld because of conflicting and insufficient evidence. Paratyphoid was suggested. Dr. Carnett suggested that the disease affecting the thigh bone was due to an infection caused by a microorganism in the joint which may arise in the absence of injury, but more frequently after injury. After examining the evidence the court makes a negative statement that "it cannot be successfully maintained there is no basis for the finding that the claimant is at the present time totally disabled and has been since the date of the accident as a direct result of the accident."

"While the law requires the relation of cause and effect to be established beyond mere possibility, it does not require its existence to be demonstrated with mathematical precision. Probability is sufficient."—*Balch v. Edward G. Budd Mfg. Co.*, 122, Atl. 1.

Directory

The Committee on Mental Hygiene of the New York State Charities Aid Association has issued a directory of the chief mental clinics maintained by general hospitals and public health agencies in the Manhattan district of New York City.

SANITARY AND HYGIENIC ADVANCE

A New Intestinal Disinfectant

A new intestinal disinfectant, $\text{CH}_2(\text{S Ag}) \text{Ch}(\text{OH}) \text{CHO} (\text{SO}_3\text{Na})$, is suggested by Lumière (*Compt. rend. Acad. d. Sc. Vol. 176, p. 510*) on the basis of extensive theoretical considerations and much experimentation, designed to discover a substance having the disinfecting action of organic silver salts but deprived of their power to precipitate proteins (and thus injure the body tissues) by the presence of a sulphur radical. The compound finally chosen is readily soluble, is not precipitated by alkali, chlorin compounds or ovalbumin and is unaltered by light. Its toxicity for the higher animals is so low that it takes one gram per kilogram of body weight to cause death while it is antiseptic in concentrations of one part to five or ten thousand. Experiments with a dog of a little over 10 kilograms demonstrated that the administration of one gram a day of the proposed disinfectant produced practical sterility of the feces in four days.

Anaerobes in Water

Meador & Bliss recovered anaerobes from 16, or 21 per cent, of 76 tubes of lactose broth, inoculated with water samples. These tubes showed gas production but no *B. coli* could be isolated. Of a total of 25 strains of anaerobic bacilli that were isolated, only two fermented lactose with gas.

Such findings throw some doubt on advisability of considering gas formation in lactose as strong presumptive evidence of the presence of *B. coli*. (*Am. J. Hyg., July, 1923, iii, 4, p. 394*)

Dietary Factor Essential for Reproduction

"If female rats are reared on the now well known 'synthetic' nutritive regimen consisting of fat, carbohydrate and protein in relatively pure, separate form to which are added an appropriate salt mixture and daily doses of vitamin A and B, normal growth and every appearance of health results." Evans & Bishop report, however, that depending somewhat on the season of the year, either a large proportion or practically all of such animals are sterile. (*J. A. M. A., Sept. 15, 1923, 81, 11, p. 889.*)

This condition the investigators consider as a dietary deficiency dis-

ease. Feeding experiments differentiate the factor concerned from vitamin C. meat, whole cereals, and lettuce leaves are some of the foodstuffs shown to contain this factor which is almost wholly absent from milk.

The factor has been extracted from protective foods and is singularly concentrated in the oil obtained by ether from wheat embryo after preliminary treatment with alcohol.

Cancer Treatment

It has been commonly assumed in treating cancer with X-rays that the characteristic changes in the cancer cells resulted from direct injury inflicted on the cells by the rays.

Nakahara has shown on mice in which cancer cells were implanted in one groin previously exposed to an erythema dose of X-rays, that the cancer cells underwent exactly the same changes histologically, supposed to result from direct injury by X-rays. Cancer cells implanted in the other groin were used as controls. (*J. Exp. Med., Sept., 1923, xxxviii, 3, p. 309.*)

Mental Factors in Industrial Hygiene

In an article dealing with mental factors in industry C. Macfie Campbell calls attention to the importance of early indications of mental disturbance in the worker. Usually mental disturbances do not come to the attention of the medical department until the later stages.

Knowledge of personal disturbances may often be secured from strange ups and downs in the wage chart of a worker. Fluctuations may often show, when checked up by a personal interview, a disturbing emotional factor on the floor where the worker is employed, an emotional conflict within the workers' personality, some distressing situation at home, or some physical ailment. (*J. Indust. Hyg., Aug., 1923, v. 4, p. 180.*)

Chaulmoogric Acid Production

"Seeds yielding large amounts of chaulmoogric acid, which has proved efficacious in the treatment of leprosy, have recently been received by the forests of Sierra Leone, West Africa, and from upper Chindwin, Northwest Burma. The African seeds are from the wild Gorli shrub. It is thought that owing to the nature of

this plant it will produce the valuable seed in a shorter time than is required by the forest trees from which the present supply of chaulmoogric oil is obtained. The seeds from Burma are those of the true chaulmoogric tree, which is native to that region. The Department of Agriculture has twice sent J. F. Rock, one of its agricultural explorers, to the native home of the chaulmoogric tree, and has secured through him considerable quantities of seed. Several thousand seedlings are now being grown in the government greenhouses at Bell, Md. These will be distributed as soon as they are large enough to withstand shipment." (*Science Service-Science, Aug. 17, 1923, lviii, 1494.*)

Defatting Acid Fast Bacteria in Vivo

In view of the recent work of Dreyer (*Brit. J. Exp. Path., June 1923, iv, 3, p. 146*) with defatted acid fast microorganisms, defatted *in vitro*, a communication from Sir Leonard Rogers to the *British Medical Journal* (July 7, 1923, 3263, p. 11) is of interest relative to the defatting of such organisms *in vivo*.

Rogers recounts the use of injections of sodium chaulmoogric acid in the treatment of leprosy. Beneficial results were also obtained by the use of sodium morrhuate and sodium soyate. Prolonged treatment with these substances produced disappearance of the lepra bacillus from the tissue and apparent cures. Favorable results were also obtained in treating cases of surgical tuberculosis with sodium morrhuate.

In the sera from three untreated nodular lepers the blood lipase was found to average only the equivalent of 0.033 decinormal sodium hydrate. In nine treated lepers the average was 0.22 or about the normal figure. Muir (Calcutta) reports finding low lipase content in severe leprosy reactions and good prognosis justified when there is high lipase content. Rogers also found that cases of surgical tuberculosis associated with low lipase content usually did poorly. He suggests that the preparations mentioned above increase the blood lipase which in turn dissolves the fatty coating on acid fast bacilli, i.e., the defatting causative bacteria *in vivo*.

Elevator Interlocks for Safety

Old presents a plea for the use of mechanical elevator interlocks (*Month. Lab. Rev.*, April 1923, xvi, 4, p. 693). Of 1,122 tragedies, 953 or 85 per cent occurred at the shaft door. Electrical interlocks are apt to be thrown out of circuit during the rush hours for the sake of getting more speed. All devices are apt to be found inoperative for various reasons unless inspected now and then. More real elevator codes are needed, but they cannot be informed governmentally without great difficulty. The author suggests that the insurance inspectors be turned loose on interlocks with the same instructions they now have on cables and safeties. "They have a way of writing out a little slip and leaving it with the owner intimating that if a certain dangerous condition is not fixed up within two days the insurance will cease."

The requisites of an effective interlock are listed.

Bacteriophage Phenomena in Acid Media

A contribution of considerable theoretical significance is made by Scheidegger (*Ztschr. f. Hyg.*, Vol. 99, p. 403), who shows that in a 37 degree broth culture containing bacteriophage but with a pH of 4.5, colon bacilli will grow, with no lytic action manifest. The lytic agent is merely rendered inactive, however, and not destroyed since adjustment to an alkaline reaction causes the normal bacteriophage phenomena to appear.

Glass Containers Best for Canned Foods

In his book on "Botulism" Dr. G. Leighton stresses the need of high and sustained temperatures to produce sterilization of canned foods. The chief points in favor of glass containers are the avoidance of metallic contamination and the ease of opening. Tin containers stand heat better and can now be closed with a small percentage of leaks. It is true that glass can be made to withstand high temperatures but the cost is thereby increased. With modern tins there is slight danger of metallic poisoning.

In editorial comment on this point the (*Lancet*, June 2, 1923, 5205, p. 1118) says: "A consideration of all the factors strongly favors the view that the risk of harmful bacterial infection, including botulism, is decidedly less if tin containers are given the preference to glass."

Metallic Salts and the Formation of Immune Bodies

The intravenous injection of the chlorides of manganese and cobalt is found by Walbum and Mörch (*Ann. de l'Inst. Pasteur*, Vol. 37, p. 396) to exert a markedly favorable effect upon the production of diphtheria antitoxin, the manganese salt being more powerful than that of cobalt. The use of manganese injections in connection with the routine production of antitoxin has greatly increased the yield in units of antitoxin resulting from otherwise similar treatment. A similar stimulating influence on the production of agglutinins is exerted by a considerable number of mineral salts, Be, Mg, Pb, Cu, Os, Ba, Zn, Hg, Al, and Mn being the most effective in the order given.

Peptone as an Aid to Vaccine Treatment

Crowe reports the use during eighteen months of intravenous injections of peptone in over seventy cases of patients who were very sensitive to vaccines. A carbolyzed saline preparation was used.

Many cases of infection by streptococci and *M. deformans*, particularly in the arthritis group, become so sensitive to vaccines that treatment is difficult and tedious. Cases cited seem to indicate that such cases when treated with peptone become desensitized and the difficulty of treatment largely removed. (*Brit. Med. Jour.*, June 23, 1923, 3206, p. 1046.)

Immunity Against Tuberculosis

The work of Sprouck at Utrecht (*Bulletin Mensuel de l'Office International d'Hygiene Publique*, Vol. 15, p. 601) has shown that a filtered extract of the tuberculous organs of infected guinea-pigs sterilized by filtration through a Berkefeld candle produce a state of allergy which may be transferred by the injection of the serum of the animal thus rendered allergic into another animal.

Malta Fever and Contagious Abortion

The extraordinarily close resemblance between *M. melitensis* and *B. abortus* (the causative organisms, respectively of Malta Fever in goats and men and of contagious abortion in cattle) includes not only practical identity in cultural characteristics but mutuality in agglutination and complement fixation. Nicolle, Burnet, and Conseil (*Compt. rend. Acad. d. Sc.*, Vol. 176, p. 1304) have however dem-

onstrated by the bold expedient of injecting living cultures of *B. abortus* into five human volunteers that this organism has no pathogenic power for man and does not even stimulate the development of agglutinins. The Malta fever organism has always been a dangerous one to handle in the laboratory and these researches open up the valuable possibility of using *B. abortus* in the diagnosis of Malta fever since both organisms react alike to the immune bodies formed in response to the presence of *B. melitensis*.

Breast Milk Dairy

Interesting activities of several breast milk dairies are recounted in a paper by Chapin. (*J. A. M. A.*, July 21, 1923, 81, 3, p. 200.)

"It is difficult to estimate the number of babies who have been benefited, as the hospitals receiving from thirty to fifty ounces a day have used the milk for a number of different cases. Taking the average amount used in private cases as a basis, I can fairly say that the milk has been given to at least one hundred babies during twelve consecutive months on an investment of \$10 for each baby to save its life."

Social Hygiene in France

France is awakening to its national problem of social hygiene says Merrill (*J. Soc. Hyg.*, May 1923, ix, 5 p. 257). Educative tracts for the army and navy eventually reach all of the male population since service is required of all young men. The first leaflet is given to recruits pending examination; the second when accepted for military service. These are retained by the young soldier during his service and on discharge he is also given a third pamphlet which stresses "clean family life, the value of health, the advantages of vigorous offspring, and the desirability of looking forward to a future of sound and able citizenship."

Detoxicated Diphtheria Vaccines

Benson has used an initial dose of 2,000 million detoxicated Corynebacterium diphtheriae, followed at three day intervals by doses of 4,000 million and 8,000 million bacilli respectively, to test the value of such treatment in cases of diphtheria. Local reaction was very slight and there appeared to be no clinical effect. Treated cases were alternated with control cases until 60 of each were obtained, after which all cases were treated making a series of 207, including 146 tested and 61 controls.

The author concludes that the treatment as outlined above has no appreciable effect in hastening the disappearance of bacilli from the nose and throat of the convalescent and that it "does not prevent cases of long persistence, to which, after an arbitrary period of three months, we apply the term 'chronic carrier.'" (*Lancet*, May 5, 1923, 5201, p. 895).

B. coli Index of Pollution of Water

The wide use of top minnows, particularly *Gambusia affinis*, for the control of mosquito breeding has led Havens and Dehler to study the intestinal flora of these fish and its effect on the *Bact. coli* index of pollution.

The normal intestinal flora of *Gambusia* in Alabama waters consists of *Ps. pyocane* and an unidentified, aerobic, lactose-fermenting, spore-forming bacillus. *Bact. coli* is not a normal inhabitant of the intestinal tract, and could not be recovered from fish grown in sewage polluted water. Moreover, fish kept in a glass jar in the laboratory in water to which large numbers of *Bact. coli* were added caused a more rapid disappearance of the colon bacteria than was found in control jars in which no fish were kept. This inhibitory influence appears to be due to *Ps. pyocane*. The authors suggest that this finding may indicate that in natural conditions the presence of a great many *Gambusia* may affect the colon index of pollution.—(*Am. J. Hyg.*, May 1923, iii, 3, p. 296.)

Mouse Typhoid Virulence

Webster, in a study of microbial virulence and host susceptibility in paratyphoid enteritidis infection in white mice has found that six strains of paratyphoid enteritidis bacilli, isolated from man and animals, differed markedly in virulence for mice. The inherent virulence for each strain for mice was not affected by repeated intraperitoneal and *per os* mouse passages.

Individual differences in susceptibility of mice to each strain and to graded doses of mercury bichloride were demonstrated and such differences appeared to be non specific in nature. (*J. Exper. Med.*, July 1923, xxxviii, 1, p. 45.)

According to Prof. Rasch syphilis in Denmark has declined 33 per cent in the period 1910-1922. The decline in gonorrhea has been much less pronounced. (*Lancet*, Sept. 1, 1923, 5218, p. 473.)

More Weight-Height Age Tables

A supplement to "Mother and Child" for July, 1923, presents new sheets of weight-height age tables, one prepared by B. T. Baldwin and T. D. Wood for children between 5 and 19 years of age, and the other prepared by R. M. Woodbury for the first six years of life by months.

Carborundum and Tuberculosis

The third study by L. U. Gardner on the relation of mineral dust to tuberculosis (*Am. Rev. of Tb.*, July 1923, p. 344) deals with carborundum dust and brings out some interesting peculiarities. Carborundum dust alone produces surprisingly slight reaction in the lungs of guinea-pigs, but the simultaneous presence of carborundum dust and tubercle bacilli of low virulence is to transform a self-limited process into a progressive tuberculous bronchopneumonia. The failure of the dust by itself to produce extensive fibrosis is held by the author to favor the theory of English pathologists which attribute the harmful effects of silica to its chemical rather than its physical properties.

Resistance of Bacteriophages

Watanabe (*Arch. f. Hyg.*, Vol. 92, p. 1) has made an important study of the resistance to heat and to chemical disinfectants of a considerable series of bacteriophages. In general the resistance of the bacteriophages appeared to be somewhat greater than that of the vegetative cells of bacteria and somewhat less than that of bacterial spores. The variations in resistance between different strains of bacteriophage (even among those operative on the Shiga bacillus) was very great. It should be noted that treated bacteriophages which had lost their power to produce bacteriolysis when sown directly on an agar plate were still "viable" as shown by the fact that they regained their effectiveness after incubation in a liquid culture of bacteria.

The Oligodynamic Action of Metallic Salts

It is claimed by Herzberg (*Centralbl. f. Bakteriol. I Abt., Orig.*, Vol. 90, p. 125) that the oligodynamic effect of certain metallic salts (copper and mercury) in high dilution is due not to direct action of the salts themselves but in the main to the fact that these salts serve to bring about secondary oxidations. The most characteristic of these effects disappear under anaerobic conditions.

Swine Plague Serum Prepared by Electro-Osmotic Method

An interesting technique has been used by Ruppel & Ornstein (*Ztschr. f. Hyg.*, Vol. 99, p. 101) in the preparation of a vaccine against swine plague. The authors claim that vaccines prepared from heat killed cultures are ineffective and that those containing viable germs are dangerous. Their own method consists in exposing the bacteria to a powerful electric current, centrifuging and using the precipitate as basis for a vaccine.

Mosquito Feeding

Tests for the source of ingested blood found in mosquitoes captured in Louisiana have been made by King and Bull (*Am. J. Hyg.*, Sept., 1923, 3, 5). General averages of the results of precipitin tests made during a season show the following sources of the mosquitoes' meals: cow, 35.7 per cent; horse, 32.6 per cent; pig 16.1 per cent; dog, 8.3 per cent; man, 4.3 per cent; and other animals (chickens and cats), 3.0 per cent.

Organism Resembling B. Pneumointes

Holman and Krock have reported the isolation from the oral cavity of man, rabbit, and guinea pig a micro-organism closely resembling *Bacterium pneumointes* in morphological appearance and manner of growth. This finding is of importance since this newly described organism may so readily be confused with *B. pneumointes*. (*Am. J. Hyg.*, Sept. 1923, 3, 5, p. 487.)

Responsibility for Milk-Borne Epidemic

On May 12, 1923, there occurred in Campheltown, Scotland, a milk-borne epidemic of typhoid fever that included over 200 cases. Investigation by the medical officer of health showed that a female worker had returned to work after an illness. In legal proceedings that followed it was not claimed that the farmer knew that the worker was still suffering from an infectious disease but that in dealing in such a commodity the defendant should have secured a medical certificate before allowing the woman to return to work. "As the defendant was apparently the first person to be prosecuted in Scotland for this offense the sheriff imposed a modified penalty of one pound with the option of seven days in gaol." (*Brit. Med. Jour.*, June 2, 1923, 3257, p. 953).

NEWS FROM THE FIELD

Adopt Five Day Week for Women

The A. Nash Company of Cincinnati has adopted a five day week and a seven hour day for the women in their employ. They also have a 50 cent wage minimum and the change in the length of the day meant no wage reduction.

In recommending the shorter work hours Mr. Nash said:

"Careful inquiry has lead me to the definite conclusion that practically all the women workers in industries are really performing the duties of a wife or are preparing to do so. The percentage of girls and women who enter industry as a life work and do not expect ever to have homes, I believe is less than 2 per cent. It is preposterous to expect a woman in any industry to do these highly specialized jobs, working eight hours per day, and prepare herself for love, husband and family."

In New York City a report on the merits of the five day week brought a diversity of opinions. One merchant said he had been working a five day plan for three years and found it very successful, while another claimed he lost money and had to raise the price of his shoes because of the lost time and delay in delivery. He said he had installed the five day week only because the labor union had been able to force him to do so.

Health Conditions Among Chemical Workers

On the basis of physical examinations made by the U. S. P. H. S. of 916 men employed in the various occupations of the general chemical industry, attempt is made by Frank M. Phillips in *Public Health Reports* to correlate the findings on the basis of income. The income range was not large and classification on this basis was made into three groups, 291 men earning between sixteen and twenty dollars per week; 230 between twenty and twenty-five dollars, and 108 earning more than twenty-five dollars per week. The age groups averaged 35.07, 35.04 and 34.99 years in the order named. Racially, the majority of the men were Americans; next in order of frequency are Poles, and next, Slavs. There were a few Italians and

persons of other nationalities.

Dynamometer readings, chest expansion, and vital capacity all increase with income. The number of children born and the number still living decrease with increase in income, while the percentage of children born who are still living increases with income. Heart disorders and pyorrhea are both high in the lower income group, decreasing as income increases. Blood count, as measured by the Tolquist index, shows no regular series in either income direction. The same statement may be made regarding overweight and underweight, hernia, defective vision, defective hearing, defective teeth, tuberculosis, bad posture and diseased tonsils.

Child Health Association Scholarship Awards

The American Child Health Association announces that its Resident and Travel Scholarships for Physicians have been awarded to the following candidates:

Dr. Charles Armstrong, Salisbury, N. C.; Dr. William W. Bauer, Milwaukee, Wis.; Dr. R. L. Carlton, Winston-Salem, N. C.; Dr. Eugene C. Chimene, Minneapolis, Minn.; Dr. William DeKleine, Saginaw, Mich.; Dr. Seymour Fiske, New York, N. Y.; Dr. Arthur M. Kimberly, Bristol, Conn.; Dr. George A. Lamont, Vancouver, B. C.; Dr. George N. Leonard, Albany, N. Y.; Dr. Marie M. Long, Memphis, Tenn.; Dr. George C. Marlette, Bay Minette, Ala.; Dr. Walter R. Moore, St. Joseph, Mo.; Dr. Russell B. Sprague, Yarmouth Port, Mass.; Dr. Thomas D. Walker, Macon, Ga., and Dr. Ruth Weismann, Dorchester, Mass.

The purpose of these scholarships is, broadly, to stimulate interest in child health work and to provide means for better training of physicians along this line.

The special committee on Physicians' Scholarships of the American Child Health Association included the following members:

Doctors Borden S. Veeder, chairman, Fred L. Adair, Arnold Gesell, William Palmer Lucas, Ralph W. Lobenstein, Alan McLaughlin, Lawrence R. DeBuys, Clifford G. Grulee, E. J. Huenckens, Lawrence T. Royster, Anna Rude, Thomas B. Cooley, Philip Van Ingen, Robert L. De Normandie, Samuel McC. Hamill, J. H. Mason Knox Jr., Henry L. K. Shaw, John M. Dodson, with whom were associated three members of the staff of the American Child Health Association.

Courtenay Dinwiddie, general executive, Ella Phillips Crandall, associate general executive, and Dr. Richard A. Bolt, director medical service. The committee on awards included the following: Borden S. Veeder, M. D., chairman; John M. Dodson, M. D., Alan McLaughlin, M. D., Anna E. Rude, M. D., Philip Van Ingen, M. D., Richard M. Smith, M. D.

Semicentennial of Public Health in Michigan

The third annual conference of health officers and public health nurses held in Lansing December 12 to 14 marked the semi-centennial of public health in Michigan. Dr. W. S. Rankin and Dr. George E. Vincent are two of the men from the outside who helped to make the occasion afford cross section of health improvement, not merely in Michigan, but in the country at large.

New England Industrial Nurses' Association

Investigative work is as much the function of the plant nurse as is first aid, stated Hiram Behr, of the Liberty Mutual Insurance Company in addressing the meeting of the New England Industrial Nurses' Association held in Boston in October. The information she gathers in regard to causes of accidents and conditions surrounding disease has a much higher potential in preventive work than is generally appreciated. And on the intelligence and completeness of her reports the management must rely for knowledge of actual plant conditions. Safety as well as other welfare activities is best administered through committee organization, and the nurse, because of her office, should be automatically a member of such committees.

Another very sane suggestion was made by Mr. Behr in the matter of goggles for eye protection. Employees are proverbially averse to wearing goggles in certain operations where their utilization is really imperative. The remedy suggested is to purchase a variety of goggles and allow the wearer some choice as to which type of goggle suits him best. He will wear the pair he selects, and is less likely to oppose wearing them when this element of choice enters into the matter.

Temperaments as causes of accidents come within the observation of nurses. A slow man on a fast machine, a fast man on a slow one, worry as a cause of absent-mindedness, all are factors to consider. And in the nurse as well, personality counts. The meeting was made the occasion of consultation on the problems of the plants whose representatives were present at the meeting.

Health Council to Survey Indians' Health

At the request of Dr. Hubert Work, secretary of the interior, the National Health Council has agreed to be responsible for an authoritative study of health conditions among the Indians, provided the money for such survey can be provided from outside sources.

American Student Health Association

The annual meeting of the American Student Health Association is to be held in Cincinnati January 1 and 2. The program will be made up of five sessions devoted mainly to an informal consideration of clinical questions or topics related to the carrying out the work with the sick or injured. A considerable assignment of time and talent has been made to the discussion of the whole question of sanitation in student living quarters and places of patronage.

To Hold Conference on Immigration

The National Industrial Conference Board called an open conference of upwards of two thousand industrialists, public officials and representatives of business and trade organizations to meet in a national immigration conference December 13 and 14. No formal vote or recommendation was taken by the conference, but a summation of the vital issues involved made in the six questions which were debated in open conference during the sessions.

Dr. Andrew Balfour Directs School of Hygiene

Dr. Andrew Balfour, who has directed the Wellcome Bureau of Scientific Research for the past ten years, has been chosen as the first director of the School of Hygiene endowed by the Rockefeller Foundation in London. Following a brilliant academic career at Edinburgh and Cambridge, he served in the South African war as civil surgeon. As director of the Wellcome Tropical Research Laboratories in Khartoum from 1902 to 1913 his reports on health conditions of that period are of first rate importance. In 1918 he undertook the organization of the public health services of the Egyptian government.

As director of the Wellcome Bureau, he has contributed valuable research on the spirochetosis of relapsing fever, blood conditions and bacteriological problems connected with

sanitation. He is joint editor of Lewis and Balfour's "Public Health and Preventive Medicine," and has published a number of monographs on sanitation. His scientific background, coupled with unquestioned administrative skill, will make him a brilliant head of the specialists identified with the School of Hygiene.

Introduction to a New Outlook in Medicine

Beginning in the November 3, 1923, issue of *The Lancet*, Sir James Mackenzie is presenting a three-part article on symptomatology which is a survey of progress in medicine and an outline of the directions research is taking in order to supply the defects of present practice. Defining disease as "the reaction of the body to a noxious agent," his attempt is to reduce the great mass of symptoms any sick man may develop to order and classification according to some definite principle, such as their relation to the mechanism or process which regulates functions. The symptoms of disease are merely disturbances of normal reflex processes. From a study of the principle of the reflex arc he proceeds to organic reaction to increased or decreased stimulation, and has evolved "the law of fluctuation," which must be considered as highly illuminative of some features of functional activity. The articles, and the research they represent, are of the greatest value, particularly because the observation is centered upon the functioning organ, and not upon the end results of disease.

Examination for entrance into the regular corps of the United States Public Health Service will be held on January 7, 1924, at Washington, D. C., Chicago, Ill., and San Francisco, Cal. Requests for information or permission to take this examination should be addressed to the Surgeon General, U. S. P. H. S., Washington, D. C.

Dental Groups Meet in Cincinnati

The meeting of the American Academy of Applied Dental Science, to be held in Cincinnati, Ohio, January 7 to 9, 1924, is called as a "Life Extension Convention," because the chief objective of the organization, and of this meeting in particular, is the province in preventive medicine of adequate care, dental and surgical, of the oral cavity and its associated parts. Dentists and surgeons, physi-

cians and nutritional experts will present a program and undertake discussions in which the general public is admittedly a partner in the effort to achieve public health, and through health a lengthened life span and a greatly prolonged period of productive activity. The program includes:

"Let Us Take the Public Into Our Confidence," by Dr. N. W. Blum, Chicago, Ill.

Address, subject to be announced, by Dr. Ray Lyman Wilbur, president, the American Medical Association, San Francisco, Cal.

Papers and clinics will be presented by the following:

Dr. George Huston Bell, Dr. George R. Lindsay, Dr. George W. Clark, Dr. Bertram Ball, Dr. Frank Tracy, Dr. A. J. Neulinger, Professor E. V. McCollum of Johns Hopkins University will present the relation of diet to tooth preservation and development.

Silver Jubilee of American Hospital Association

Under the presidency of Asa S. Bacon, the twenty-fifth annual conference of the American Hospital Association convened in Milwaukee October 29. A series of very practical reports on important subjects included membership classifications, community relationships, building and construction, equipment and maintenance, and on flooring. A new note of co-operation was sounded with reference to the standardization program initiated by the American College of Surgeons. In presenting this subject, Dr. Franklin H. Martin urged that the hospital and medical minds concentrate upon the determination of what are necessities and what luxuries in hospital service. He sounded a warning note against extra charges for such essential services as laboratory investigation. The extra charges should be for the luxurious room and super-added comforts, that matters entering into scientific care at whatever cost must be supplied to every patient under hospital supervision.

The difficulties of record keeping as analyzed by Dr. Malcolm T. MacEachern command the interest of institutional administration bodies everywhere. Of the institutions that have failed to meet the minimum requirements as to records, Dr. MacEachern stated that such failure was due in 57 per cent to deficient organization, and that 52 per cent failed because of poor laboratories or inadequate records. The problems of the small institution had a very able advocate in C. S. Woods, superintendent of St. Luke's Hospital, Chicago, who suggested that the American College of Surgeons permit the

hospital of twenty-five to fifty beds to suggest from their own difficulties pertinent phases of hospital work for special study by the college. Dr. Caroline Hedger made a very spirited criticism of certain administrative features of hospital training schools for nurses. Careless platitudes will not serve to clarify the situation, she said. The necessary information on what is actually being done will have to be forthcoming before constructive improvements can be instituted. An investigation of the subject in Chicago revealed such confusion of records, and such imperfect understanding of the subject that in not a single instance could it be determined what it costs to feed the student nurses, not to mention the desirability of learning what it costs to train a nurse.

The dispensary was discussed chiefly from its position as an adjunct to the hospital, though the various papers revealed the desirability of knowing more about services, distribution, personnel, responsibility to management, and other vital matters pertaining to dispensary matters. Certain it is, according to Dr. Alec M. Thomson, that the dispensary group is everywhere coming to be regarded as the exponent and advocate of preventive medicine. Interesting questions were raised on the subject of health examinations in general, and the matter of charges to patient direct, to employees, or to the insurance company demanding the health inventory was fully canvassed. It was generally agreed that the broader application of dispensary findings is greatly hampered for lack of follow-up machinery.

Dr. Asa S. Bacon will serve the association as president during the current year. Dr. E. S. Gilmore, superintendent of Wesley Memorial Hospital, was named as president-elect; Dr. J. B. Franklin, superintendent, Baylor Hospital, Dallas, Texas; Dr. C. W. Munger, superintendent, Blodgett Memorial Hospital, Grand Rapids, Mich., and Emily Loveridge, Good Samaritan Hospital, Portland, Ore., were made first, second and third vice-presidents, respectively.

Industrial Medicine Breaks in Germany

The Berlin correspondent of the *Journal of the American Medical Association* reports that industrial physicians in Germany, because of delayed payments of their fees, are hardly able to exist. Many physicians have already found themselves compelled to refuse credit to sick benefit societies and to treat patient members of these

societies only for cash payment, which means a cessation of their contracts.

The medical profession demands immediate governmental regulation and legislation in favor of the industrial benefit societies, which are in such great difficulties. If the inability of the industrial benefit societies to pay is not lessened in the immediate future, the entire medical profession will no longer be able to co-operate in sick insurance, and a total breakdown of social institutions will then be inevitable.

Pharmacists have recently taken the same attitude as the physicians toward the sick benefit societies. Their resolutions state that since the sick benefit societies are unable to pay, the majority of pharmacists are in danger of ruin; in consequence, if this condition continues, they will be compelled to suspend their contracts with the sick societies and to furnish medicines only for cash. In the face of this threat the treasury department has succeeded in bringing about a temporary agreement. The sick benefit societies have made a monetary advance to the pharmacists with which to renew their stocks, and have further assured them that they will pay the amounts due for medicines more promptly than heretofore.

To Extend the Use of Fish as Food

At Bologna recently was held a Fish Congress designed to extend the use of this food. From the chemical point of view interesting questions were taken up, especially the relations between the saltiness of the ocean and the migrations of fish beds; and, on the chemical properties of fish oils, notably from the point of view of their richness in vitamins. The value of certain oils, especially the oil of cod liver, is attributed to their richness in vitamins, and it seems to be quite certain that the ocean is a medium particularly rich in all sorts of vitamins.

Along the same line Mme. Randoine has recently pointed out that the source most rich in vitamins is the oyster. It is the anti-scorbutic vitamin which the oyster contains in the proper proportions that has never before been found in a single living organism. The oyster could be a source of vitamins not only for consumption, but to facilitate the investigations on their isolation.

The American Electrochemical Society will hold its spring meeting in Philadelphia, April 24 to 26, 1924.

U. S. Uses Three Million Pounds Insecticide Annually

The powdered heads of a flower, pyrethrum, was the world's first insecticide and was for many years man's only weapon against the ravages of fleas, flies, cockroaches, ants, lice, bedbugs, and other vermin of the invertebrate type.

Like many other of the world's conveniences, its discovery came in a totally unexpected way. The flower, showy in appearance, is even now cultivated for decorative purposes. It was through this attraction that its insecticidal action became known—some withered flowers having been cast out, the householder was surprised to find a considerable collection of dead insects lying about, which led to the discovery and its subsequent utilization of the product. The natives who used it first were puzzled by its action and for a long time refused to divulge its source or method of production. John Powell writes the story of pyrethrum in the October 31 issue of *Drug and Chemical Markets* and reports the researches of the last decade that have revealed the cause of its toxic properties. Pyrethrum owes its insecticidal value to the presence in the pollen of a volatile oleoresin. This is present in the greatest amount in the closed flower heads, which must be gathered early in the season at the time the insecticidal value is sealed in the flower by the process of nature.

Pyrethrum is the ideal household insecticide for the reason that it is not poisonous to humans and may, therefore, be safely kept where there are children. Also its use is suitable where other preparations would be obnoxious. It is non-odorous and will not stain fabrics.

The import of pyrethrum flowers, both Japanese and Dalmatian combined, indicate that America alone uses more than three million pounds a year.

Mine Rescue Standards

A tentative study (Technical Paper 334) of "Mine Rescue Standards" prepared by a committee appointed at the International Mine Rescue Standardization Conference of September, 1921, has just been issued by the Bureau of Mines. The study is particularly valuable in bringing out the physiological effects of gases, adequate methods for the detection of the gases encountered in the mines, the requirements of breathing apparatus and the physical fitness of men to wear breathing apparatus.

Edward L. Keyes Heads Social Hygiene Association

Dr. Edward L. Keyes was elected president of the American Social Hygiene Association, succeeding Dr. Hermann M. Biggs, deceased, at the annual business meeting of the association, which was held at the national headquarters October 26, 1923. Dr. Keyes has been identified with the social hygiene movement for many years. His scholarships and general standing assure in his appointment a continuation of the leadership of the social hygiene movement under the successive administrations of Dr. Charles W. Elliot, Dr. Abram W. Harris, Dr. William H. Welch and Dr. Hermann M. Biggs.

Digest of the Labor Laws of the State of Arkansas

A Digest of the Labor Laws of the State of Arkansas as in force at the close of the legislative session of 1923 has been issued by the Arkansas Bureau of Labor and Statistics. The general labor laws are fully annotated and in addition a subject classification refers to a large number of laws which directly or indirectly affect labor.

Delaware Improves Laws on Child Labor

Delaware has reduced a ten-hour day, fifty-four hour week, for children under 16 to an eight-hour day, forty-eight hour week, and raises the minimum age in dangerous occupations, including mines and quarries, from 15 to 16. A street trades clause, applicable to Wilmington, prohibits boys under twelve and girls under fourteen from engaging in street occupations, and prohibits such employment for any child between seven p. m. and six a. m., and during school hours.

Warehousing and Transportation Economies in Distribution

As a part of the general battle against waste, the Domestic Distribution Department of the Chamber of Commerce of the United States is making a comprehensive study of warehousing and transportation. The impulse toward the use of public warehouses, proper storage is a science—the care of food, wearing apparel, drugs and other commodities in transportation is no longer a mere piling of goods in ill-lighted ramshackle old buildings, fit for nothing else—sanitation as well as economy is served by classification and consolidating shipments.

Role of Oxygen in Food Spoilage

The discovery of Pasteur of the relationships of microorganisms to organic decomposition led to a sort of mental stampede which Long directed all investigation into food spoilage along bacteriological lines. Gradually, however, an accumulation of observation points to the fact that definite chemical changes take place in foods which in time render them unfit for consumption. This type of oxygen spoilage is discussed by Thomas M. Rector in the October issue of *The Canning Age*. The rancidity of nuts, he says, is chemical rather than biological in nature. Nuts packed in oxygen-free containers in his laboratory early in 1921 are still in perfect condition.

Oxygen accounts also for the rancidity of edible oils. Olive oil chemically pure, and containing less than one-tenth of one per cent of moisture became highly rancid under conditions that promoted oxidation. The spoilage of butter is complicated by biological factors, but experiments with butter fat confirmed Rector's thesis that the presence of air is the cause of its decomposition.

Frozen eggs, salad dressing, dried milk, catsup, fish, and olives are listed among the foods which commonly deteriorate through the oxidation reaction. Without minimizing the importance of bacteria, yeasts, and molds in food spoilage, the subject of oxidation *per se* is always to be given full consideration.

American Institute of Chemistry

The American Institute of Chemistry represents the first organized effort of American chemistry to apply the scientific method to the study of men engaged in the chemical industry.

Deploing the lack of reliable data on the personnel, classification, and distribution of chemically trained men in industry, the Institute has set itself the task of appraising the chemical engineer in industry, of determining the kind of technical men the present situation demands, and estimating whether the 1,350 graduates that graduate annually from 129 technical institutions are going to posts where their best talents are likely to be utilized. The question of apprenticeship before or during lecture work introduces cooperative courses between colleges and industry as a means of promoting practical training. Such procedure would shorten apprenticeships on the part of graduates after they have entered industrial positions.

Chemists Asked to Study Coast Water Pollution

David M. Neuburger, LL.B., president of the International Coast Anti-Pollution League of America issues a call to the chemist to purge industry of its contamination of coast waters. He looks to the laboratory rather than to legislation to correct the poisonous effluents of oil refineries, and oil burners or oil carrying vessels of chemical and dye works of straw board factories, pulp mills, tanneries, steel mills and countless other agencies that contribute to industrial waste, while it causes ruined property values, destroys marine life that serves as food and brings disease to a degree that is appalling.

That the matter is urgent is brought out in the report of the Interdepartmental Committee on the Pollution of waters, which found pollution by oil to be present in all of the thirty-five places investigated on the Atlantic and Gulf coasts.

Make Study of Refrigeration

A scientific congress recently held at Strassburg, had for its object the study of refrigeration from the standpoint of production and utilization. Particular mention is made in *Industrial and Engineering Chemistry* of the explanation in this congress given to the utilization of freezing in the preparation of vaccines and in medicine.

There was also proposed a means of using low and constant temperatures in research laboratories. Without descending to temperatures as low as those of liquid air, it is certain that in the investigation of temperatures as low as 0 degree and—50 degree C., the chemical reactions and phenomena are not sufficiently known and merit further study.

United States Finds That Drug Habit Is Costly

That a total annual loss of more than \$1,825,000,000 is suffered by the United States through the expense of the drug habit and the loss of the services of the addicts, is the statement of Dr. Carleton Simon, special deputy commissioner of the New York City police department in an address before the Women's City Club of that city. A further cost, not estimated in dollars and cents, is involved in the fact brought out by Dr. Simon that of the many thousands of addicts examined in the service of the New York City narcotic squad about 85 per cent have criminal records.

HEALTH PUBLICATIONS REVIEWED

The Communicable Diseases

The aim of Dr. A. J. McLaughlin's book, and presumably of the whole series of which it forms a part, is to provide knowledge in regard to public health problems in the form which will appeal not to the professional specialist on the one hand nor to the general public on the other, but to the increasing group of intelligent citizens, physicians, lawyers, clergymen, teachers, social workers, club women, business men and business women, who have become interested in public health and desire to know something about it without taking time to wade through exhaustive and highly technical treatises. In the present volume Dr. McLaughlin discusses the general causes of disease and the development of epidemiology with the underlying principles of quarantine, isolation and disinfection and of infection and immunity and then proceeds in the latter four-fifths of the volume to discuss briefly and succinctly each of the communicable diseases. In connection with every disease there is given a definition, a brief outline of the history of our knowledge, a discussion of the specific cause and mechanism of infection and the principal methods of control. It is needless to say that the reader of this volume can rely upon the information furnished as reliable and completely up to date and Dr. McLaughlin has rendered a very real service in presenting it in such compact and effective form. It should not only be of value to the class to which it is specifically addressed but should also prove a useful reference book for the public health worker engaged in field activities.

Harper and Brothers, New York, 1923.

The Making of an Executive

A. Hamilton Church has brought forth his valuable book on "The Making of an Executive," the most comprehensive statement we have seen on the character and qualifications of the high class business executive. The changed standards of recent years no more permit haphazard methods on the part of the executive than they leave to carelessness or chance the details of equipment, layout, organization or inspection.

Whatever else he may become, the modern executive must be first a fact gatherer and a fact user. What facts are necessary tools of management, how they may be collected, analyzed, interpreted, and reduced to a graphic representation which makes them possible to operate as control measures throughout the plant.

The relationships of the executive are defined with regard to the (1) office, (2) purchasing and bookkeeping, (3) the factory, (4) marketing, (5) promotion of quality and quantity, (6) finance, (7) the function of industrial research. Satisfactory industrial relations are seen as the logical outcome of vision and right method.

Questions of welfare are incidental to many topics—Church makes it clear that undue fatigue on the job is to be removed through expert investigation—micromotion study, if necessary—of the problems involved; worry is avoided through proper division of functions; and marketing safeguarded through preventing defined quotas.

Physical welfare is insured through engineering methods; psychic welfare through adequate personnel work—selection, training, and satisfactory initiation periods. Church expressly favors methods of management that reduce friction to a minimum by committee organization that permits the freest possible expression of the workman. Stern practice fully demonstrates a self-governing atmosphere eventually lifts a considerable burden from the management.

Plant hygiene must be fully adequate and all health safeguards provided. But welfare work must never be done under the guise of a gift from the management. He goes so far on this point as to say that safety depends upon always remembering that the primary object is an industrial one. "Just so far as it is found profitable to improve conditions, it should be done, and no further."

He is very explicit that the machinery of the plant shall be sensitive to the intelligent manipulation of the executive, and that the policy of a concern is its concrete expression added to this exhaustive and accurate knowledge and an executive is made.

It is little wonder that executives

are scarce, that most concerns feel they must develop their own men to administrative positions, and that successful heads for going concerns are so hard to replace or supplement that the National Industrial Conference Board is making a specific effort to devise cooperative effort between schools and industry for the provision of a suitable background to develop the type of trained man the situation calls for.

D. Appleton and Company, New York, 1923.

"Eating Without Fears"

Some few years ago a farmer died at the ripe age of 100 or thereabouts, and the newspapers gave much space to his antemortem declaration that his long life was due to his total abstinence from tobacco. A well-known "Columnist" paralleled this statement with the remark that Gladstone attributed his long life to the fact that he was never without the companionship of Lady NICOTINE:—and at the head of the two columns put the caption "Take your choice".

The author of this book, C. F. Scotson-Clark, has been a happy healthy man, and has enjoyed many good things in life. The tale he tells is most interesting reading, especially his collection of stories, and considered as a piece of narrative it might even win a prize.

But—of its scientific value the least said, the better. If it were not so humorous it might be dangerous for unfortunately when figuring foods, sauce is not always sauce.

Nicholas L. Brown, New York, 1923.

Home Sanitation in England

Domestic sanitation and house drainage by Henry C. Adams, is a very good presentation of English practice in regard to building construction and house drainage with brief chapters on refuse disposal, heating, lighting and ventilation. The book is a little archaic in some respects in its assumption of danger from ground air and sewer air and its value to American readers is naturally diminished by the fact that the details of plumbing practice differ considerably in the two countries. The chapter on refuse disposal is of rather special interest, giving excel-

lent regulations for the disposal of refuse by dumping, valuable data in regard to the operation of the Shore-ditch refuse destructor and a description of some interesting methods which have been worked out in England for the salvaging of scrap metal and other constituents of house refuse.

Birth Control. What Is It?

Dr. Lydia DeVilbiss, formerly director of the Division of Child Hygiene, State Health Departments of Georgia and Kansas, has written a very clear and effective account of the significance of birth control from the standpoint of eugenics, international relations, public health and mental deficiency with a temperate plea for such modifications in federal and state legislation as will protect the conscientious physician in his relations to his patients while providing effective safeguards against illegitimate abuses. The book is worthy of the serious attention of public health workers.

Small Maynard and Company, Boston, 1923.

Health Building and Life Extension

We are glad to publish herewith a letter from Dr. Fisk, the Medical Director of the Life Extension Institute. The subject with which Dr. Fisk's book deals is of the greatest importance and we heartily agree that specialists in the field of public health will find in this work data of very real value which it would be difficult to get so easily from any other source. Our reviewer was considering the book from the standpoint of more general readers and literary impressions are necessarily more or less subjective.—Editor.

My dear Sir:—My attention has been called to a review of the book "Health Building and Life Extension" appearing in the August issue of THE NATION'S HEALTH.

It appears evident that on hasty consideration of this book the reviewer, probably misled by the title, assumed that it was intended wholly for a popular audience. While I maintain that there is a message for the general public in this book, nevertheless it is primarily a scientific study of ill health in industry and an adaptation of the important information secured through the surveys we have made of these health problems to the general population.

The aim of this book has been to furnish original studies and important fundamental statistical information as to the prevalence of certain physical impairments leading to disease, and an outline of the rational remedial measures of all kinds that might be applied to the correction of these conditions and the upbuilding of individual and public health. A good deal of time and money was spent in the collection of this information and the preparation of this material and I know that the work has high value to me personally as a book of reference, and therefore should have value to all physicians, health workers, students, and writers who deal with these health problems. However, the book is not a mere technical array of statistics and there is no good reason why people of average culture who are at all interested in health problems should not find the book an accessible source of information on these topics.

Very truly yours,

EUGENE L. FISKE, M.D.

Medical Director

Life Extension Institute, Inc.

Human Character

Why does Lady Maria pay a ten-minute call on Lady Jane in the afternoon; why does a person in a state of excitement find it necessary to communicate the cause of his excitement to everyone he meets? Why does the billiard marker spend his holiday watching billiard matches? Why does a murderer go back to the scene of his crime? Why does the patient retail to his visitors full details of his complaint? Why did Herbert Spencer write a system of philosophy?

The answer is the same in every case; it is because the sentiments of the individual concerned find natural relief in expression of this kind. Feeling, not reason, governs the lives of men. Subjective, not objective, reasons explain their conduct and what they do under excitement is done primarily to please themselves.

The endeavor to prove all man's actions, reasonable and logical instead of instinctive and emotional, has resulted in the elaborate distortions of the earlier psychologists, for the fact that much of our education does not "take"; and foreordains the failure of reformers that propose the destruction of society by a single coup, and to rebuild it at a single stroke by a better plan. Nearer the truth comes Hugh Elliot in his recent book on "Human Character."

The fundamental point to appreciate about human character is that motives are activated by instinct; that intellect is an acquired tool to give them expression; that mental life is merely a sequence of thoughts and feelings, following each other in endless succession; that what we attend to depends upon outside stimulus; that the predominant mental tone is what gives cast to character; and that character itself is a fluctuating thing, and at most is an abstraction—a name for the average mental manifestations.

A man must interpret life on the basis of his own experience. The rich see life very differently from the poor, and people at the two extremes understand one another only on the basis of common experience. As every individual has a fixed limit of mental capacity, so is there apparently a fairly definite range of pleasure-tone than cannot be passed. Above that limit the nervous tension cannot be maintained and further stimulus leads, not to further pleasure, but to pain. Accessions by fortune, of power, etc., according to Elliot, rarely bring the happiness that was anticipated from them; for few individuals realize that their "possible range of happiness is physically limited, and very likely is not much greater than that which they already enjoy."

On this basis Elliot is most illuminating in his discussion of predominant motives on the relative paucity and general feebleness of voluntary actions, on germs, on vice and crime, and on the influence of disease. He has much to say of the bad effects of mental excitement during states of fatigue. The whole thesis tends to put psychology on a constitutional basis and to show the futility of trying to force the mental processes, either social or individual.

Longmans, Green & Co., New York, 1922.

The widely known Publication No. 12 of the National Committee for the Prevention of Blindness, "Eye Hazards in Industrial Occupations," first issued in 1917 has been revised, greatly broadened in scope, brought up to date, and is to be available for general distribution by January 1, 1924.

"Food, Teeth, and Health," is the title of an educational pamphlet issued by the Child Federation of Philadelphia, which treats of prenatal foundations for good teeth, of foods

conductive tooth development, and of hygienic care.

The digest of a report of a survey of "The Public School System of Arkansas" brought out as Bulletin, 1923, No. 10, but the Bureau of Education, is in general an indictment of the general inadequacy of the present system. Of the sanitation of urban and village schools, the statement is made that "sanitation is deplorable, toilet rooms dirty and poorly ventilated. It is only fair to say that in some towns the sewer service is poor. This does not, however, excuse the unspeakable filthy conditions found in some toilet rooms. The sanitary conditions, at high noon, in the dairy barns of the agricultural high schools visited are better than in the toilet rooms of ninety per cent of the schools investigated.

Farmers' Bulletin No. 1354 of the U. S. Department of Agriculture is a brochure on "The Yellow-Fever Mosquito," prepared by L. O. Howard, chief of the Bureau of Entomology. The work is fully illustrated and makes interesting reading.

The study made of medical education in the United States during 1920-1922, by the Council on Medical Education and Hospitals of the American Medical Association is brought out as Bulletin No. 18, Bureau of Education, 1923, by the Bureau of Education over the signature of N. P. Caldwell, M.D.

New Books on Vital Statistics

The summer of 1923 has been unusually prolific in the production of important works on Vital Statistics. With the three books reviewed below, with the new edition of Whipple which appeared a year ago, and with the revision of Newsholme's English classic, promised for the near future, the shelf devoted to this field of public health will be well stocked.

"Statistical Methods," by Truman L. Kelly' is primarily for advanced workers in the statistical field who use such methods as a device to portray the facts of their group investigation; and particularly for those who resort to mathematics to aid in discovery of new truths. The book treats the subject of statistical methods logically and on a sound basis; including graphics, dispersions, probability, curve fitting, measures of relationship, correlation, and special problems. It should be very useful to serious workers in statistics, because

of its clear presentation of the underlying mathematical principles and even perhaps to the mathematician for its treatment of various theoretical phase of the subject.

A work which will prove of vital interest to a wider group of physicians and sanitarians is the "Introduction to Medical Biometry and Statistics," by Raymond Pearl.¹ If we do not always agree with Professor Pearl we always follow his brilliant and stimulating researches with keen interest and profit and this fruit of his teaching experience will prove of inestimable value. The book begins with an admirable review of the landmarks in the history of Vital Statistics and reveals the fact that Pearl (like Kelly) is an ardent disciple of Karl Pearson. After a helpful treatment of the mechanics of handling statistical data and representing them in graphic form the book gives us perhaps the clearest and most effective presentation available for the biologist of the probable error concept, and the measurement of variation and correlation, illustrated throughout with data from the researches of the author. An appendix presents a valuable table of specific death rates by sex and age and cause for the Registration Area for the year 1910. This book should be invaluable for every student and practitioner of vital statistics.

The third book on our list, "The Principles of Vital Statistics," by I. S. Falk' is the outgrowth of a course given by the author to students in the public health nursing course offered by the New Haven Visiting Nurse Association in cooperation with Yale University, and has an even wider appeal than either of the others. It deals with the results rather than with the methods of vital statistics and the purpose of the book is "to introduce the student to the subject of Vital Statistics, to describe the more important procedures and sources of information which are commonly utilized in statistical inquiries, to indicate certain outstanding evidences and conclusions which statisticians have derived and which are of interest to students and workers in public health, and to discuss briefly certain cautions which the untrained statistician must observe in the treatment of vital statistics." Dr. Falk has prepared the first satisfactory text on vital statistics simple enough to be used by students lacking a mathematical background and has gathered together an unusually valuable collection of concrete illustrative material.

The book is written with unusual clearness and in places with real literary quality. For the public health worker in general, as distinct from the professional statistician, it is perhaps the best book we have; and even the student and specialist in statistics will find it a useful supplement to Pearl's treatment of fundamental theory.

A Vindication of Vivisection

A second edition to which important additions have been made appears in "A Vindication of Vivisection," title of a brochure edited by Francis A. Tondorf, S.J., Ph.D., and being a compilation of a course of lectures on animal experimentation by such men of authority in medical and other sciences as Simon Flexner, William Creighton Wood, William H. Arthur, Thomas S. Cullen, George Tully Vaughan, George B. Foster, and others. The work completely offsets the stupid and stereotyped arguments offered in opposition to biological methods of investigation.

Bridgeport Department of Health Laboratory

(Continued from page 857)

Floor plan of the Laboratory of the Department of Health, Bridgeport, Conn. The layout is planned with due regard to working convenience.

scopical examination, blood counts are made, examinations are made of gastric contents and urinalyses are carried on as routine.

(3) *Examinations of water.*—A constant check is kept on all public and private water supplies in the city. Examinations are also made of the waters of private swimming pools.

(4) A considerable part of the division's time is devoted to the examination of milk samples. Each milk sample is examined for bacteria count, for total solids and for fats; whenever the results from total solids and fats indicate added water examination is made with the dipping refractometer.

(5) *Miscellaneous work.*—Among the miscellaneous functions of the laboratory are the examination of food supplies, the analysis of liquors for the police department, the analysis of grease and tankage for the municipal reduction plant and the distribution of supplies to physicians.

The laboratory staff consists of a director, a bacteriologist, a chemist, two laboratory technicians, a clerk, and one other person who assists in the general work of the laboratory. It has been the policy of the Board of Health Commissioners to appoint as director of the laboratory only per-

sons whose academic and scientific education and preliminary training have fitted them for the responsibilities of the position. The laboratory has had but two directors. In each instance she has been chosen for her personal qualifications as well as for technical and scientific training. The director has entire freedom to organize and plan the work of her division. All orders for new material and equipment originate with the director, although purchases are made subject to the approval of the health officer and daily reports are made to him. The director supervises and plans the work of the various members of the laboratory staff and all questions of departmental routine and procedure are referred to her for adjustment. The director is responsible for the expense account of the division and for the accuracy of its records and reports.

The bacteriologist is responsible to the director for the examination of all specimens for diagnosis in diphtheria, tuberculosis, gonorrhea, Vincent's angina, etc., for the examination of milk sediments

for microorganisms, for the carrying out of the Widal tests, for blood count and blood cultures, for animal inoculation, for typhoid plating, for the examination of urine sediments, the interpretation of the Wassermann test and many other duties. Like the director the bacteriologist was chosen for her aptitude and fitness for the work and for having had scientific training and preliminary experience fitting her for her position.

The chemist and assistant bacteriologist are responsible for the staining of all slides, for the smearing of sputum, for the transplanting of all permanent cultures and for counting milk plates. The chemist makes all water analyses, analyzes liquors, and food samples of other kinds, and is responsible for the preparation of stains, media,

and reagents. She carries on as well those analyses of greases and tankage made to check the by-product output of the municipal reduction plant.

Laboratory Technicians

There are two technicians employed in the laboratory. Neither of these had previous experience in laboratory work. They were chosen by the director from among suitable applicants and have been trained by her for the work they have to do. It may not be amiss here to state that this plan has proved very satisfactory indeed. The

Room for chemical analyses. Reserve room on other side of partition.

first technician is responsible for the smearing of all diphtheria cultures and is under the direction of the chemist for the preparation of diphtheria media. She is also responsible for the routine chemical analysis of urine, for the preparation of all outfits going out to the culture stations, and for keeping the milk records on the charts. The second technician has the care of the culture stations under his charge, the work of milk analyses, the plating of milk and the chemical analysis of milk. He also has charge of the animals and the daily collection of specimens from culture stations.

The clerk has general charge of the laboratory office, the entering of specimens, the care of files and records, and the reports which are made to physicians either by letter or over the telephone.

There is also one laboratory assistant or person of all work who washes the glassware, does odd jobs about the laboratory and gives a helping hand when asked.

Functional Organization

So much for the laboratory lay-out, its equipment, working force and functions. To maintain the laboratory for the year 1922 there was expended \$9,230. During this period 34,986 examinations and analyses of various sorts were made. Not long since some one tabulated laboratory costs of certain cities on the basis of cost per examination. Bridgeport's experience would give a per examination cost of approximately twenty-six cents. This, however, would seem to be rather a crude method of arriving at the efficiency of a laboratory or for that part of its value to the community; it means little other than so many examinations were made and so much money expended in making them.

The laboratory comes into contact with so many of the other activities of the health department that it is to say the least, difficult to determine a graded standard by which its true worth may be estimated and given proper valuation. We know that the expenditure of a certain sum of money rightly directed will lessen the deaths among the babies of the city and we can estimate the value of that work in terms of the infant death rate. No such standard is provided through which we may judge of the value of the laboratory's work. There is, however, one way in which the worth of a laboratory may be estimated and that the extent to which the services it has to offer are used by the community. Much of the lab-

oratory's work originates within the department of health, milk analyses originating from the division of milk inspection and control cultures originating from the division of communicable diseases are instances in question. But we find that a large part of the laboratory's work originates from the physicians of the city and that the measure of this work is constantly on the increase. The character of the work so carried on has largely to do with the control of communicable disease, properly a task in which the physician should be aided by the department of health, and with the laboratory helps which the department has to offer physicians in the diagnosis and control of disease not necessarily communicable.

We have felt here in Bridgeport and we have had no occasion to change our minds, that outside the routine work of the department, the value of the laboratory to the community is going to be in direct proportion to the confidence it inspires among the physicians of the community and the degree to which it is used by them in the control of disease and the relief of sickness and suffering.

We have tried to inspire this confidence among physicians. We have as advisory consultant to the laboratory the director of laboratory service in our largest hospital, a man of the highest professional standing and attainments. We have placed in charge of the laboratory persons of previous training and have chosen those who would inspire the confidence and the respect of the medical profession. No other factor has been allowed to influence the selection of a worker in our laboratory. And we have provided a laboratory thoroughly and well equipped with every facility for giving to the physicians of the city the aid they require or may request. And we think our plan is working out very well indeed and that our laboratory is a factor for good in the community.

Feeble-Minded and Insane in Ohio

Fifteen thousand feeble-minded persons in Ohio are in need of supervision, training, control and segregation according to the State Department of Public Welfare (Publication No. 22).

A five year program looking toward the solution of this problem (Publication No. 21) is offered by Dr. E. M. Baehr and Miss N. M. Thornburgh of the Bureau of Juvenile Research. Seventy per cent of those receiving

aid as dependents are either feeble-minded or show evidence of some other gross mental disorder. Seventy-five per cent of the delinquents and criminals are feeble-minded, psychopathic or insane in varying degrees. Thirty per cent of the inmates of the industrial schools, reformatories, and state penitentiary are mentally deranged to such a degree that their present place of confinement is unsuited to their needs. The recommendations provide for a new and complete training school for defectives capable of caring for 2,000 patients. This number should never be exceeded. The state has already appropriated money for the purchase of land for such institution and there should be no longer delay in securing a site.

It is recommended that the Bureau of Juvenile Research be expanded into a Bureau of Welfare Research and made the center of an intelligent campaign against feeble-mindedness and other mental disorders; representatives of this Bureau to be stationed in the industrial schools and penal institutions. Mobile psychiatric clinics should be provided. A return to the indeterminate sentence law is urged, the determining to remain entirely in the hands of the Department of Welfare.

Legal provision should be made for the voluntary commitment of the feeble minded and the limitation on the number of voluntary commitments now allowed for insane and epileptic cases removed.

An editorial in the *Lancet* (May 12, 1923, 5202, p. 961) reports severe criticisms by Haldane, Collis and others of Robson's paper on miners' nystagmus, previously abstracted in the Digest for July.

Twenty-five new playgrounds were opened in the District of Columbia, July 1, under the direction of the District Playground Commission.

Directory of Neurologists and Psychiatrists

The National Committee for Mental Hygiene is compiling a directory of all physicians in the country who are practicing neurology or psychiatry, with autobiographical information concerning each, so far as possible. It will be similar to the directory prepared by the committee during the war, but will bring to date the neuropsychiatric resources now available. This information will be used to meet the demand.

Eating for Health in the American Tropics

(Continued from page 863)

To prepare it begin as with *arroz abanda*. Then add a chicken which has been jointed and braised and enough water to cover it. Simmer until cooked, remove the chicken, season the liquor with Spanish saffron and cook the rice in it. Serve on a large platter with the yellow rice as a base and the chicken pyramided above. Decorate with pimiento. Sometimes mushrooms, olives, and shellfish are added, in fact almost any liberties in this direction may be taken if the basic formula is adhered to.

Game birds, ducks, snipe, swan, wild pigeons, wild turkey, and pheasant, are frequently obtainable and are very good. The American custom of eating turkey at Thanksgiving and Christmas is taking hold in Central and South America and the domestic variety is being produced in increasing quantities.

Eggs are usually plentiful and cheap. It is an amusing sight to see an old egg woman wrap her hand about an egg, hold it in front of one eye, peer through it at the sun and solemnly announce its authentic freshness. Nobody ever heard of an egg failing to pass this censorship, but the ceremony is always a part of the sale. Cold storage eggs are almost the only ones obtainable in certain tropical ports and many of them are veritable museum specimens. When scrambled with cheese or canned tomato their antique flavor is considerably disguised.

Oranges peeled to the pulp, impaled on forks and imbedded in ice are an almost universal breakfast dish "on the lap of the line" and pineapple of exquisite quality often closes a dinner. Here it should be interpolated that in most tropical countries breakfast as we know it is non-existent. The first meal of the day, *desayuno* in Latin-America, consists of fruit, a hard roll or tortilla, and coffee extract of the general potency of hemlock juice but well diluted with hot milk. Breakfast (*almuerzo*) is served at eleven o'clock and runs the gamut from soup to small black coffee. At seven o'clock comes dinner (*comida*), a repetition of breakfast plus dessert (*dulce*). Supper (*cena*) is only served once in a while and is a festal occasion beginning about midnight with

weird sausages eaten with jam and ending with an ice (*hielado*) of sourop (*gannabano*), cashew (*marañón*) or star-apple (*caimito*). Grape fruit, mamey apples, mangoes, mangosteens, cherimoya (a sort of vegetable library paste), and anona are all used as breakfast fruits. Mangoes are a laxative and should be avoided during outbreaks of intestinal disorder. They should be peeled with a knife before eating as irritating substances in the rind produce a very disagreeable eruption on the lips, face and fingers of susceptible persons. Papaya, a sort of melon growing in great profusion on a tree, is a most useful fruit. Before using, it is "bled" of its milky sap by making a series of shallow incisions through its rind and allowing it to stand for a day or two. This fruit is reputed to contain a vegetable digestant, papain, which is not unlike pepsin in its action. The natives believe that tough meat may be rendered tender by wrapping it in the leaves of papaya. This fruit is used as are melons at home or cut into balls or cubes and served with French dressing.

Alligator pears (*aguacate* or *avocado*) in many places, for example in Mexico and Tumaco, Colombia, are delicious and may be used as breakfast fruit or salads. Bananas, like the poor, are always with the tropical dweller and they vary in color and size from the little canary yellow finger banana to the gigantic dark red variety. They have the decided advantage of being protected against contamination by their rind or peeling. A delicious way of cooking them prevails in Kingston, Jamaica. They are peeled, laid in a shallow, greased pan, lightly sprinkled with sugar, baked, and served with a cocoanut milk, not cocoanut water, that's another thing, but the milk obtained by treating grated cocoanut with boiling water, placing the scalded cocoanut meat in a muslin bag and squeezing out the milk. Served icy cold imbedded in the banana jelly which is produced by the baking they make a splendid dessert. Plantains are a sort of left-handed cousin to the banana and are classed on tropical menus as vegetables. Boiled and then baked or fried, they are palatable and easily digested.

In some tropical places good potatoes are produced locally. In others they are imported and the supply at times runs out. Sweet potatoes have a high carbohydrate content and a certain amount of sugar and in some localities are plentiful. The so-called "wooden-potato" or yam is a homely looking root which on section is either white or yellow. The former variety is preferred by Americans and when thoroughly boiled and put through a potato ricer closely resembles the Irish potato, for which it forms an excellent substitute. The same may be said of breadfruit and manioc or cassava also known as yuca. It should be borne in mind that *yuca dulce* is the variety to be used in this way. *Yuca amarga* contains prussic acid and must be washed thoroughly before it is grated, sun-dried and sold as tapioca. Yampi resembles them and is a useful ingredient of soups and stews.

Digressing again, it may be remarked that soup and its more solid cogenor stew, is a staple portion of most tropical diets and one on which much thought may be profitably expended. They are highly nutritious, easily absorbed and a sovereign remedy for fatigue. Far from being too hot for a warm climate, their fluid heat is very grateful to the diner. The native soups may contain almost anything from vegetables and meat to spices and poached eggs. Usually their fat content is high, in fact most native dishes abound in grease since butter is rarely used in native homes and fats must be secured in other ways. The American housewife will know how to eliminate superfluous fats from soups and stews but this should not be done too rigorously since most of the local butters are not above sanitary suspicion and the tinned imported products frequently require working over to eliminate their axle-grease-like flavor. Some of the Danish butters, however, are really good and not too expensive. Cold storage butter from the States is rather temperamental, one time being first quality and the next disagreeably flavored. In many places the only fat easily obtained is cocoanut oil. If not rancid, it is not at all bad although the appetite may

tire of its characteristic taste.

A large variety of squashes and squashlike vegetables may usually be had. *Chocho*s or *chayotas* resemble the summer-squash in flavor and when boiled or served au gratin they are good food.

Beans are a basic part of the diet. Fresh string beans may usually be secured and in every market there is a wide choice of the numerous varieties of dried beans, peas, and lentils. The red bean is boiled and served with fluffed or fried rice. The latter is prepared by cooking the rice with fat or olive oil and a little water in an iron pot without stirring. The bottom layer is allowed to brown and when the rice is removed, care is taken to extract this layer intact. When the rice is placed in the serving dish this brown cap surmounts the whole and is considered a great delicacy. Dried beans are frequently beaten to a pulp with a pestle and mortar, moistened with a little soup stock and one well beaten egg. The mass is then thoroughly beaten much as we do in making beaten bread. The secret of this dish lies in the amount of man-power and time put into the beating. The mass is then patted out into thin cakes and cooked in boiling deep fat as is a doughnut. The cakes puff up like a pouter pigeon and are dainty, crisp, highly nutritious food.

Tortillas are made in much the same way. One buys fresh, wet-ground corn meal called *masa* at the market and sprinkles a little finely ground cheese on it. Thin cakes are patted out of this, being well beaten between the cook's palms which are dipped in cold water at frequent intervals during the process. The cakes are dropped into deep fat and if prepared properly they "rise." There is another variety of tortilla which is not raised, being cooked on a griddle much like our hoe cakes. Similarly, very thin cakes are prepared from cassava meal.

Coffee is served at practically every meal but it is not the beverage as we know it in the United States. The beans are given a blacker roast and in some places it is served as a black, syrupy extract which newcomers do not know how to use. There is always a tendency on their part to drink too much of it with resultant harm to the nervous system and the digestive apparatus. The seasoned tropical dweller only takes a little and that generally well diluted with hot milk. Coffee should be roasted in

small lots, just enough for a day or so, and ground immediately before using. In this way the aroma of the coffee is retained and the product greatly improved. Tropical coffee is almost universally dripped.

Chocolate is a highly nutritious beverage whose use is widespread in Hispano-America. Its color depends upon the length of time that the cocoa beans from which it is made are fermented before milling. It is ordinarily purchased in the form of little cones, each of which contains enough for one large or two small cups of chocolate. To prepare it properly, put the requisite amount of milk and chocolate and a little sugar in a sauce-pan, bring to a scald with constant stirring. Take it off the fire and beat it by rotating a notched stirring stick between the palms. Scald and beat again twice, adding one or two drops of vanilla.

Lack of Refrigeration

In most tropical towns it is considered infra dig for a white woman to carry a basket. An accompanying servant does that. This may create a temptation to purchase more than enough supplies of fresh foods for one day. This should be firmly resisted since the deterioration of food-stuffs is apt to be so rapid that no experienced tropical housewife will buy more than is currently needed and she makes it the invariable rule never to use left-overs. Refrigeration is a great problem in many places and even where ice is to be had, it is sometimes difficult. Screened "safes" hung in a breezy place out of the sun are sometimes used but it is better never to keep putrescible foods under these conditions.

Water may be kept in screened "ollas or jarros" which are made of unglazed clay and by the evaporation of water from their surface lower the temperature of their contents. All water of doubtful purity should be boiled before using. The large stone filters so frequently seen are worse than useless as water purifiers and may furnish breeding places for mosquitoes. Milk, except the tinned or dried varieties, also should be boiled since there are few tropical places where safe fresh milk is obtainable. A notable exception to this rule is Panama where market milk of high sanitary quality is produced. Goat's milk in places where Mediterranean fever does not exist is a good substitute for cow's milk but the danger of milk in the tropics is not so much

a matter of the milkee as the milker.

The tropical cook-house is frequently disheartening to the housewife fresh from the neat, orderly kitchens at home. Ants parade around it and cockroaches almost as large as mice skuttle about the shelves and floor. Flies sail in and out of the open windows. A barefooted, half-clad cook shambles listlessly about with her hair hanging wispily. She may speak no English or perhaps she has a whining dialect alleged to be our mother tongue but resembling not the language of Shakespeare. Sometimes the cooking is done in some shaded spot in the open; sometimes over a charcoal brazier set in a doorway; sometimes, as in Chiriqui, in a chimneyless room on a stone altar where burning hardwood sticks are being constantly advanced toward the cooking vessel from which they radiate; perhaps, as in Venezuela, there is a stone cooking table with small gratings let into the top beneath which burns charcoal fed in through holes in the edge of the table, perhaps it's a good old American cook-stove or range, or oh joy! oh rapture! a gas or electric range, as in Balboa.

The ants should be attacked with sodium fluorid and the cockroaches by a spray of pure carbolic acid one part and kerosene 5 parts. The kitchen should be screened and flies which gain admission because the cook will insist on keeping the screen door blocked open, "In order that the flies may have a chance to get out," captured by a sticky solution made by heating together castor oil thirty-five parts and resin sixty-five parts and applying hot to wires suspended from the ceiling or stretched across the room. This sticky mixture may also be spread hot on sheets of paper but a better way is to dip an old upholstery spring fastened to a block of wood with it. Wires which become covered with flies may be cleaned by dipping them in boiling water and lye or soda. Unceasing warfare and immaculate cleanliness is the price of freedom from insect pests in the tropics. Food and garbage must be promptly removed and if rats or mice get into the house they must be ruthlessly combated with traps and poison. Perhaps after a long period of exhortation and exemplification, the cook may be brought to a temporary realization of her duties in the keeping of a spotless kitchen. Her vocabulary knows not the word hurry and the impatient northerner who tries to accelerate her is attempting

KOTEX

Bring home a box or two—

Women find Kotex most convenient, both for their own use and that of guests. It is customary now to keep a supply always on hand. An excellent safeguard—and a *real economy*.

For Kotex is cheap enough to throw away and easy to dispose of by following simple directions found in each box. It solves a laundry problem. It provides comfort and insures poise. It completes milady's toilette.

Kotex is made from fine gauze and Cellucotton—the wonderful absorbent material which is so much more effective than cotton. These sanitary pads come in two sizes—Regular and Hospital—and have generous tabs for pinning. They are sold everywhere by good stores that serve women.

The very first box of Kotex usually forms a new habit of comfort and standard of convenience. Bring home a box or two—

Ask for them by name

Regular Size, 12 for 65c
Hospital Size, 6 for 45c
(Additional Thickness)

Kotex cabinets are now being distributed in women's rest-rooms — everywhere — hotels, office buildings, restaurants, theaters, and other places — from which may be obtained our Kotex with two safety pins, in plain wrapper, for 10 cents.

INEXPENSIVE, COMFORTABLE, HYGIENIC and SAFE — KOTEX

the impossible, almost the suicidal. But she has no eight hour schedule, her wages are low, she does not fret about any free-born rights, and household engineering to her is a closed book. This explains why the time element is so little considered in the preparation of the dishes described in this article.

There is a tendency to overbalance the diet in the tropics in the direction of the carbohydrates and in some places the roughage element is too low. On the other hand in many localities there is too great a preponderance of meats. A balanced ration is just as necessary as in the Temperate Zone. There is no particular reason why the Nordic should not have just as good food in the tropics as elsewhere provided the housewife will study the food problem carefully and use brains and energy in its solution. Intelligent marketing and selection of menus, and cleanliness of servants, kitchen and utensils are of basic importance. The big element of healthful eating in the tropics though, is the energetic application of brains and ceaseless vigilance.

Radio Hazards

Considering the many people who are building and operating radio sending and receiving sets, the number of accidents has been small, but those that have occurred have been of such a serious nature that warning is not out of place. An admonition of caution and a statement of the possible hazards and means of avoiding them are included in a recent report of the Radio Hazards Committee of the National Safety Council.

"On the whole, the underlying causes of most accidents in connection with radio apparatus are ignorance and carelessness. Many persons, using radio equipment, do not know the dangers of the apparatus; others, conversant with hazards, forget them in their enthusiasm.

"The handling of antenna wires after they have become charged by falling on or touching high voltage power and light wires (or by those wires falling on the aerials) has resulted in severe shock and death. The collapse of antenna masts due to improper or insufficient guying has led to such cases as well as to serious falls.

"An outdoor aerial is not necessary for efficient reception of radio messages. The use of an indoor aerial eliminates contact with outside power and light wires and the hazard of climbing to unfamiliar places. A

lighting arrester, while not absolutely necessary, should be installed.

"Storage batteries have caused several accidents, due to the fact that after charging, expelled oxygen and hydrogen gases (an explosive mixture) have come in contact with an open flame or have been ignited by crossed wires. Spilling or leaking of electrolyte (usually sulphuric acid) has ruined interior furniture and caused severe body burns.

"There is ample current capacity in dry cell batteries to produce a fatal shock, but ordinarily the voltage is not sufficient to force this fatal shock through the body. Some 'B' batteries, however, have as high as 350 volts which would cause a severe and possibly a fatal shock to anyone coming in contact with both main terminals when making or breaking the connection. A good general rule for avoiding shock is to use one hand only and be sure the body is nowhere grounded.

"The sending station should preferably be located in a building of substantial construction and should derive the current necessary for operation from a source other than the supply to the building for other purposes. Where such stations have been located in private dwellings and apartment houses and secured their operating currents from the building supply lines, fire and accident hazards have sometimes resulted. The antenna should be located so that, should it fall, it would not touch any light or power lines.

"The poles supporting the antenna should be guyed in four directions, the guys should be provided with insulators and the poles should be located with respect to the edges of the building roof so that there will be no hazard of falling off the roof.

"The lead-in wire should be kept five inches away from all parts of the building. The same air space should be provided for all ground wires. Splices and joints in the antenna span and lead in wires, unless made with approved clamps or splicing devices, should be soldered. All antennas and lead-in wires should be of copper or approved clad steel not smaller than No. 14 B & S gage. The lead-in wires should enter the building only through non-combustible, non-absorptive insulating bushings.

"As protection to the transmission equipment from lighting, it is plain that a lighting arrester is not practical for sending sets. Radio engineers have recommended the installation of a double throw knife switch,

the specifications to correspond with the standard 60 ampere, 600 volt switch, with the exception that a slate base is not recommended.

"Overfusing a circuit or replacing a fuse with copper wire, pennies or other illicit methods is analogous to tying the safety valve of a boiler so it will not operate. In both cases, the protection which is depended upon to prevent accidents is removed. Such practice is indefensible.

"Generally speaking, fire insurance companies will not be affected adversely by the installation of radio receiving sets even with outdoor antennas. It is suggested, however, that those who wish to make certain of this point, call up their insurance broker who will either give verbal consent to the addition or will issue a radio permit endorsement for the fire insurance policy without charge or change in rate."

Intraperitoneal Administration of Antitoxin

The intraperitoneal administration of diphtheria antitoxin has been suggested by Platon for use in selected cases among infants and young children. (*Arch. Ped., Sept. 1923, xl, 9, p. 575.*)

Absorption by the intraperitoneal route is not, of course, as rapid as absorption by the intravenous route but it is approximately five times as rapid as absorption following intra-muscular administration. Within an hour it is more than sufficient to neutralize the toxin in the blood in any case of diphtheria. Absorption by the intraperitoneal route is more rapid in infants than in older children and local discomfort is absent. This method is said to be particularly suitable for advanced cases where suitable veins for intravenous administration are lacking and in moderately advanced cases in which intravenous injection is not considered necessary or advisable but where more rapid absorption is desired than can be obtained by the intramuscular method.

Teeth as Portals of Infection

J. Mendel (*Ann. de l'Inst. Pasteur, Vol. 37, p. 537*) has succeeded, both with rabbits and monkeys, in producing tuberculous infection by inoculating tubercle bacilli, in some cases of relatively low virulence, into the pulp cavities of the teeth.

Automobile accidents cost the lives of 221 persons in New York state during the month of October.

To Relieve Weak Foot, Muscular and Ligamentous Strain

The symptoms of these conditions are tired, aching feet, tender heels, cramped toes, rheumatic-like pains in the legs and bodily fatigue. For such cases Dr. Scholl's Foot-Eazer should be prescribed. It is light in weight, self-adjusting, comfortable to wear and gives just the right pressure at the right spot. By removing the unnatural strain, which is always present in cases of weak foot and incipient flat-foot, Dr. Scholl's Foot-Eazer gives immediate and lasting relief.

Dr. Scholl's Foot-Eazer is only one of

Dr Scholl's *Corrective Foot Appliances*

Leading shoe dealers and surgical instrument houses in all parts of the world, through special training are prepared to follow accurately physicians' instructions. There is a Dr. Scholl's Corrective Foot Appliance for each specific foot condition, adjustable to meet the individual requirement of each particular case. Dr. Scholl's Appliances are worn in the regular size shoe—no special shoe—no plaster casts required; for heavy persons, for growing children, and those constantly on their feet.

Food Legislation and Inspection

(Continued from page 870)

it through the usual channels of trade, although a small portion could have been used for food purposes if cooked within a few hours.

Since 1917 other changes have been made in the character of foods examined and fewer examinations for decomposition have been necessary.

Unusually able men have in the past been connected with the analytical force of the department. These include the late Dr. Edward S. Woods, the celebrated toxicologist and medico-legal expert, the late Dr. Charles Harrington who at the time of his death, was secretary of the state board of health and professor of hygiene at the Harvard Medical School, the late Dr. Goessman, professor of chemistry at Massachusetts Agricultural College and former president of the American Chemical Society. The late Dr. Charles P. Worcester, analyst at the time of his death, was also secretary of the Harvard Medical School. The late Albert E. Leech, author of "Food Inspection and Analyst," was analyst of the board for ten years, and at the time of his death was the chief of the Denver Laboratory of the United States Department of Agriculture.

In the early period of the work, there were four analysts part time, and three inspectors. In 1892 there were one analyst part time, one assistant analyst and three inspectors. In 1898 there were one analyst full time, one assistant analyst, and three inspectors. In 1907 there were one analyst, three assistant analysts, and four inspectors, and today there are one division director, who is the chief analyst, five assistant analysts, and seven inspectors, as well as a clerical force of six.

The increase in force is not due to any increase in adulteration of food, but is due to laws made to control possible sources of adulteration and to prevent the manufacture of adulterated food. It is also due to added duties imposed by legislation, such as the cold storage law, slaughtering laws, bakery law, the law relating to the sale of mattresses, and, recently, the pure coal law.

The Eighteenth Amendment of the Constitution has played a considerable part in the increasing of the work of the division. The law requires the department to make, free of charge, an analysis of any liquor submitted by police or certain other officials provided that the results of the analysis

will be used for prosecution in state courts. Under this law there are now submitted to the department nearly six thousand samples of liquor per annum, while prior to July 1, 1919, such samples seldom exceeded one hundred per annum.

A word regarding prosecution may be of interest. In Massachusetts any citizen can enter a complaint in court for violation of a criminal statute, and he has the right to appear in the lower court, as the representative of the Commonwealth. This procedure is used in the prosecution of all cases the food and drug division handles; and the employees of the division, none of whom are lawyers, enter and try these cases, not in their official capacity, but as citizens of the Commonwealth. Only in a very unusual case is an attorney hired, there being but five such cases in the past nine years. About ninety-five per cent of the cases are disposed of in the lower court. In instances where appeals are taken, the case is handled by the district attorney.

The food laws have been of value to the citizens of the United States. They have cut down the sale of adulterated foods and drugs, they have reduced unfair competition in trade, they have been instrumental in preventing spoilage in food transportation and disposition, and have been of benefit to those merchants who desire to sell articles of superior quality.

Science Outstrips Medical Teaching

"The growth of medical sciences in the last fifty years has radically changed the prerequisites, subject matter, methods, duration, and cost of medical education," states a report issued by the Rockefeller Foundation. "Knowledge and the technic of its application have increased enormously. Demands on the time and energy of teachers have grown heavy and exacting. Expenses for laboratories, teaching hospitals, salaries, and supplies have mounted rapidly. Under the new system apprenticeship systems have disappeared." Nevertheless, private practitioners still constitute the great body of clinical teachers in medical schools the world over.

The new conditions, condensing the report, have produced the typical modern centre for teaching and investigation—the unified university

medical school, in a stimulating scientific and cultural environment, controlling its laboratories and hospitals, under the direction of full-time staffs. Few university schools in the world have reached or approximated this standard. The tendency, however, in all advanced countries is toward this university type. Traditional preconceptions, the vested interests of practitioner professors, unfamiliarity with new ideas and methods and lack of funds are the more obvious obstacles to progress.

To attempt to teach the medical student all that is known about health and disease is, on the face of it, absurd, the writer points out. There is complaint already that too much is being forced upon him and that he has no time to think for himself. It is agreed that an undergraduate medical course should not seek to give a complete education, but to ground the student in fundamentals of knowledge and technique and to inspire in him a scientific spirit and a sense of social obligation. These necessary limitations are resulting in the development of graduate teaching. The time is coming, the writer predicts, when all surgical and other specialties and advanced laboratory work will be taught as graduate subjects.

The raising of standards, with consequent lengthening of the medical course and its increased cost to both individual students and to society, gives rise to a number of serious questions, the article sets forth. Some advocate shortening the combined elementary and secondary school period by two years, to reduce the age at which a physician may begin his career. Another suggestion is that more scholarships be granted to promising students. There is agitation for a shorter, less expensive type of training to maintain the supply of general practitioners, on the theory that many superficially trained doctors will settle in rural districts which now lack resident physicians. Many foresee a system of local hospitals serving surrounding areas by out-post dispensaries and visiting nurses.

While some differentiation may be expected between physicians who go into general practice immediately and those who pursue graduate studies in the specialties, there is no reason to suppose that standards of medical education will be lowered.

Constipation ~

In obstinate or recurring cases, recent clinical evidence indicates the value of fresh yeast

EVERY physician has had numerous unsatisfactory experiences with the ordinary laxative drugs—from cascara to mercurial purgatives.

While in no sense a substitute for proper exercise or fresh vegetables, Yeast is a highly valuable dietary adjunct in cases of obstinate or recurring intestinal inactivity.

It is not habit forming. It produces no digestive disturbances. It can be prescribed as a part of the regular daily diet for as long a period as may be necessary.

Recent investigations on the effects of fresh Fleischmann's Yeast showed that it acts as a bowel *regulator* rather than as a purge, since the "normal"

subjects tested experienced no increase in weight or frequency of stool, while "the condition of every individual who had any degree of constipation was improved."

Best results are obtained by eating one cake half an hour before a meal or the last thing at night—followed by a glass of water. If desired, the yeast may be first dissolved in water, milk, or fruit juices.

A new authoritative book: written by a physician for physicians. This brochure discusses the manufacture, physiology, chemistry, and therapy of yeast. A copy will be sent you free upon request. Please use coupon addressing The Fleischmann Company, Dept. Y-26, 701 Washington Street, New York, N. Y.

Report of Progress in Public Health Laboratories

(Continued from page 873)

for its object the improvement of different phases of the work so that standards may be raised and maintained at a high level throughout the various departments. Continual study is directed towards perfecting the procedures used in the production and standardization of the therapeutic and prophylactic products sent out from the laboratory. Classification of meningococci, typing of pneumococci and the production and standardization of antimeningococcus and antipneumococcus serums are included in this work as well as investigations on *B.botulinus* and botulism before botulinus serum was produced, standardized, and distributed. Studies in hydrogen-ion concentration as used in the adjustment of media and in antitoxin plasma have engaged considerable attention.

It has been necessary to investigate and standardize some of the reagents and materials used in the laboratory. Thus, the production of amboceptor in a mule has been of great practical value. Much study has been expended on the improvement of the complement fixation test for tuberculosis and has recently yielded results which should make this test an extremely valuable diagnostic aid in public health work.

Certain investigations have been undertaken in connection with outbreaks of diseases in different parts of the state. Thus, during the last two or three years, extensive work has been done on poliomyelitis, influenza, and infectious jaundice.

In addition, research has been carried on in some of the fundamental processes of infection and immunity. This includes studies on the coagulating properties of blood, on the effect of osmosis upon the movement of leucocytes and the action of toxins on leucocytes.

Many other city and state laboratories are carrying on equally important research problems to a greater or less degree than those which have been cited as examples; but the subjects above mentioned indicate the importance and diversity of problems which confront different communities. The laboratories of the larger cities have been more actively engaged in research as the funds and personnel of the smaller cities are usually inadequate for this important service.

Attention has been directed to the helpful researches in Massachusetts, New York, and Michigan. The development of parasitological technic, as a routine measure in California under the able direction of Dr. Kofoid is also of interest, particularly in view of the discovery of several cases of amebic dysentery in a small area of Connecticut and the request by physicians for diagnostic assistance from the state laboratory. According to the thirty-seventh biennial report of the State Board of Health of California, 1922, the number of routine examinations for intestinal parasites in stools received from various physicians in the state and from infirmaries, hospitals, and health centers increased from 3,572 in the year 1920-21 to 6,431 in the year 1921-22 and the number of persons examined from 784 to 1,730.

Movable Laboratories Utilized

Certain other states, as Indiana and Michigan, have profitably utilized movable laboratories in addition to the central laboratory for touring the rural areas and resort sections. Dr. King, state health commissioner of Indiana, writes that a truck so arranged as to carry all the equipment for a water and milk laboratory, is at present used in connection with a sanitary survey which the state is making of the lake resorts of northern Indiana. The first location of this movable laboratory was at Warsaw, the laboratory being established in rooms connected with the office of a group of physicians. From this laboratory as a center a survey was conducted over an area from fifteen to twenty-five miles in each direction and included some eight or ten lakes. In addition to the laboratory force two field inspectors are assigned to the work, one for collecting samples of water and milk and the other for making official inspections of food producing and food handling establishments. In addition to this work a complete survey is made of sanitary conditions, including garbage and sewage disposal. Orders are issued by the field inspectors wherever in their opinion such orders are indicated and following the compilation of the survey, orders are issued by the State Board of Health covering those things that cannot be handled by a field inspector.

Following the survey of the lake resorts, Dr. King states that it is planned to make surveys of rivers and a large number of small summer resorts and recreation places that are being developed all over the state.

In Michigan, according to a statement in the *Engineering News-Record*,¹¹ it was concluded by officials of the health department that "Trained men equipped with a portable laboratory for making examinations of water and food supplies was the best means of looking after summer resort sanitation." In 1921, four men with a motorized laboratory and roadster inspected 123 resorts and hotels in ten counties.

Opportunities for research are few in the hustle-bustle of the routine laboratory. At the same time it is felt that such work is exceedingly stimulating to the average worker and will result in considerable benefit to all concerned. Perkins,¹² in an admirable review of the field, points out the value of research and the actual need of that forerunner of applied knowledge. He also suggests the possible cooperation of a public health laboratory with a university staff, to the probable advantage of both parties and the world in general.

The subject of standardization is very often agitated and the need for something along that line is shown by the recent investigation by Dr. Slack of the various methods employed for the same kind of operation in different laboratories in and near Boston.¹⁶ He concludes that some method of supervision or of mutual association of diagnosticians should be devised to insure the use of uniform technic and as a control on the accuracy of the work. The woful lack of certainty in diagnosis before, and the fairly good correlation of results after simple standardizations are strong arguments for uniformity in technic. Of course it is true that some bacteriologists are happier when they employ their own modifications to a given method, and perhaps that fact is of value sometimes in the promotion of research.

In New York State,¹⁷ standardization is emphasized, while the Division of Laboratories and Research is fostering self-reliant country and small city laboratories rather than attempting

—that is precisely what

Anusol Suppositories

do and why for over a quarter of a century they have remained the standard and most widely prescribed remedy for the relief and treatment of Hemorrhoids, and the rectal disturbances leading up to Hemorrhoids.

The booklet reproduced above, has recently been mailed to every Physician, Hospital, Sanitarium, etc., in the U. S.

Have you received your copy?

Do you wish a complimentary trial quantity?

Manufacturing Laboratories
BLOOMFIELD, N. J.

to do all the diagnostic work for the whole state in the central laboratory. Considerable care and supervision is given, however, to this whole subject of uniformity in technical methods and to the types of personnel employed in state laboratories. Needless to say, there should always be the closest co-operation between state and municipal or county laboratories.

The keynote of the whole public health laboratory problem is of course to have efficient personnel, and then to get the physicians, milk inspectors, and others to utilize the advantages of the laboratory by sending samples^{1a} and by becoming educated to a correct interpretation of reports. This is one goal toward which we should direct our course in the future, more vigorously than in the past, for the pioneer work in demonstrating the importance of such procedure has already been done. A great mass of the public, too, more than we usually realize, become interested in public health activities through the channels of the laboratory, as in milk and water reports, special disease studies, and the like. This fact is illustrated in a weekly newspaper of a small town which repeatedly during the past summer published letters from the lay people, and an editorial, requesting reports on the water supply of the community.

It is sometimes necessary and often as difficult, not only to educate the general public, but also the common council, by whose grace the health department usually receives its annual budget. Not infrequently, the members of this important body have little idea of the function of a public health laboratory, or of the type or scope of work performed. Sometimes this difficulty may be overcome by special efforts on the part of the laboratory health department staff to engage the interest of the council members in this branch of work. This was illustrated by the visit of a councilman, upon the health officer's invitation, to a city laboratory in charge of the senior author. As the visitor was shown the weekly records and various laboratory operations in progress, he manifested surprise, in spite of the fact that he was a physician, that so many different types of work which had a direct bearing on the health of the community could be undertaken in a small laboratory. His interest subsequently stimulated wider use of the facilities available, increasing the volume and scope of work as well as official support of the laboratory. This experience might not be applicable elsewhere, of course, but it is believed that laboratory workers have definite

opportunities, especially in small cities, which are not always recognized.

Lastly, we cannot urge too strongly the importance of trained personnel, and standardization of both laboratory work and technic. Much depends upon the laboratory findings in these days of modern medicine, and physicians, as well as the public, may expect reports deserving of confidence, as a result of work skillfully performed.

18. It has been found that a well equipped laboratory can make about one hundred twenty-five examinations of all kinds per one thousand population annually at a cost of not over forty cents per specimen. Several laboratories are now making more examinations than this at a lower cost, but the above figures also allow for considerable research.

A unique school of nursing is announced by the *Lancet* as being conducted at the Pirquet Clinic, Vienna, where physicians are given instruction in the everyday care of the child. Four physicians are entrusted with the care of the ward, doing all the nurses' work. They must wash, bathe, and tidy the children; serve their breakfast; give them medicine; make temperature charts; and prepare for the morning rounds of the professor. The night duties, at present performed by a nurse, will soon be allotted to the student physician who must serve two months in all at the school. The new curriculum proposes a year of internship for the physician before he may engage in the practice of medicine, and attendance on this school is made compulsory. It is proposed that hereafter the physician and the mother will no longer work at cross purposes because the physician is ignorant of domestic exigencies.

Garbage Disposal in Central America

Garbage disposal in the capital of one of the Central American republics. On the whole this is better garbage collection and disposal than is usually seen in the land where the "gallinaza" or buzzard is the unofficial and unpaid scavenger. It was found at Panama, P. F., that the burial of garbage was a cheap method of disposal and when the garbage was well sprinkled with a "Invidette" of phenol and resin soap as it was put into the excavation, there was relatively little fly breeding. Reduction and incineration entail a considerable expense and some method of treatment in fly-proof fermentation cells would be far less attractive to rodents and flies.

Hospital sterilization in your own surgery

THE calamity of unsterile goods in surgical cases is too great to risk halfway sterilizing methods. To transport them to a hospital may be safe enough, but is a nuisance.

The surest way is to have positive pressure sterilization available at your own office, clinic, or surgery. The Castle Vertical Autoclave sterilizes in steam at fifteen to twenty pounds pressure, using the same technique as in the hospitals. Dressings come out absolutely dry. Send for more details.

The Adolescent Girl Becomes a Health Asset to the Home

(Continued from page 878)

Interesting enough courses, one may say, but are they used? Are the children interested, and do the parents approve?

Taking these up in reverse order, we find if we avoid the question of sex hygiene, a subject not at present ready for public teaching, parents like the idea. We also find that all churches approve.

As to interest, one only needs to go into one of the classes, or, better to see the mothercraft group graduate, to find out how enthusiastic are pupils and parents as well. The mother instinct is strong in girls and, while dolls may be all right, how much more attractive is caring for a full-sized manikin as one would care for a baby. You know they even name the dolls. For example, one is called Rose Standish, another Adelaide Wood, and a third Polyanna Knowlton. Another proof of interest is the very definite evidence of knowledge at the completion of the course. That means interest by both pupil and teacher. It is because the mothercraft group most assuredly liked it that approval of this particular course is given. Material for similar courses is also good, well-planned, and satisfactory, as can be

Miss May Bliss Dickinson, director and founder of the mothercraft courses in the New Bedford Schools.

seen from the work of the Red Cross.

Regarding practicability. The girls in our groups apparently used the lessons about as fast as they were given as was brought out through certain essays, one girl practically taking charge of a baby for a week and with great success; another made use of the ideas for improvising and brought comfort to a baby who perhaps might have otherwise numbered among the summer mortalities. Actually the girls have seen the vision of real service through this work and to them it is far more interesting than mechanical work with mere dolls. As a matter of fact our chief trouble with mothercraft as demonstrated in our work in New Bedford was being unable to accommodate all who wanted it.

The two courses outlined, one infant welfare, the other home nursing, actually represent the solution of definite needs and in a public health program they fill a place which, if uncared for, will contribute to no small extent to the defeat of some of the strongest health programs. When the New Bedford method is used, the added factor of the support of strong interested organizations, gives further prestige to the work and to my mind success is the only word which properly describes such plans properly carried out.

The age is a practical one. Perhaps, after all, instruction in conserving human life may be more valuable than entire devotion to the muses.

involves for the nurse careful study of the situation in order to get hold of the outstanding problem. Usually the problem is complicated by the fact that in most country places the board of selectmen serves also as the board of health. They are busy men with little time for detail, without a trained agent, and it is not unusual to find confusion in the handling of communicable disease. Such was the condition at Deerfield when they employed a community nurse.

The large Polish population, with very little regard for quarantine laws and regulations, had so confused the health administration that after a few months it was not a difficult matter to persuade the board to adopt the communicable disease regulations as recommended by the department of public health. The writer was appointed as their agent. At the same time post cards were printed for the physicians to use in reporting cases. Once in contact with the family, in the first visit a plan is made for isolation and instructions are given for the care of the patient and the care of the family, the home placarded and regulation of quarantine explained.

The placing of placards had been rather dreaded as it seemed too bad to have the school children associate the nurse with sickness and being "shut in," but when after the physician had made a diagnosis of scarlet fever, one small girl said to her mother, "Anyway, the nurse will visit us and put a bright red card on our house," my fears were allayed of becoming unpopular because of these measures. Needless to say the mother did not feel quite so joyful.

The reported cases are the most easily cared for. It is the hidden and suspected cases that require the most careful work. This is particularly true when dealing with a foreign population.

Being health agent gives one the authority to say, "You must have a physician or the house will be quarantined." This results in a physician being called in to make a diagnosis. It also gives the authority for taking a culture on the suspicious looking throat of a school child. In this way several cases of diphtheria have been found. This would lead to embarrassing situations with the physicians but for the fact of their splendid cooperation. With this and the backing of a good board we seem to be getting good results.

A study of the four years, during which the writer has served as health officer, a very satisfactory decrease in communicable diseases has been

The Nurse as Health Agent

FLORENCE A. SIMPSON, R.N., HEALTH AGENT, SOUTH DEERFIELD, MASS.

THE caption of this article indicates an interesting change and development in the field of nursing. The responsibilities of the health officer or agent may be among the duties which the public health nurse in a rural community is called upon to assume. In such a case one of the primary problems confronting the nurse will be the control of communicable disease. During recent years there has been a great change in the methods of control applied to these infections. Many nurses received their training when things, rather

than persons were considered the source of infection. After accepting the newer interpretations it then becomes a question as to the extent to which modern methods can be introduced into the community.

It is not strange to find persisting in most country places some fears and superstitions that we have learned to discard. Even the trained nurse was somewhat appalled when the reaction against fumigation began and this practice was pronounced of little value.

Public health work in a new place

shown. For eight months in 1919, we had ninety-eight cases, in 1920, seventy-six; in 1921, fifty-three and in 1922, but thirty-five.

There are other parts of the work not so interesting and satisfactory. Reports of insanitary conditions are investigated, but many times the places in question are more untidy than a real menace to health. Things requiring action are referred to and taken up directly by the board. It is always a source of help to refer problem cases to the state department of public health through the district health officer and with his help a course of action can be decided upon. With this splendid support of the local board, physicians, and the state department of public health, a nurse must welcome the added responsibility of "health officer" in order to demonstrate a wider scope of usefulness to the rural community.

Jersey City Starts Drive Against Home Sweat Shops

Exploitation of children by sweatshop operators is to end in Jersey City, according to announcements from the National Child Labor Committee. On the basis of inquiry instituted in the first instance on suggestion of the Reverend Corrado Riggio, head of the Italian Department of Goodwill Community house, who supplied a list of names for investigation, a study was undertaken by Mrs. Nellie Smith, head of the Bureau of Vocational Education, under the direction of Health Officer Hagen. There have been found 934 children working under home sweatshop conditions, and the report of the health officer carried a picture of such deplorable conditions that action was brought at once against the worst offenders, judgment carrying jail sentence instead of fines. Actions to date have covered 316 children and 273 adults, representing 161 families.

Pennsylvania Reports Fewer Industrial Accidents

According to a statement issued by the Department of Labor and Industry of Pennsylvania, a total of 112,746 inspections were made during 1922 by the Bureau of Inspections, of which number 88,340 were routine inspections according to the block system plan, and 24,406 were special investigations. The number of violations of labor laws for the year

reached an aggregate of 8,817, while 181 prosecutions were instituted.

The Division of Accident inspection shows a total of 1,890 fatal accidents in industrial, public service, and mines, as compared with 1,924 in 1921. Industrial accidents alone, however, not including mine accidents, numbered 732 in 1922 as against 644 in the preceding year, an increase of nearly 14 per cent. Rather a serious lapse in measures of protection against accidents in industry is reported as existing in the industrial work of the boys at Huntington Reformatory and special regulations were made and enforced by the Division of Accident Inspection.

During the three years ending January 1, 1923, 3,023 persons reported as disabled and residing in Pennsylvania have been offered the services of the State Bureau of Rehabilitation, 2,279 have registered with the bureau, and 1,014 have been placed in suitable occupations, many thus placed having been given both school training and training on the job, says the statement. Of the 2,279 persons registered only fifty-three were females.

The character of the disabilities of those registered with the bureau during the last three years is indicated as follows: Hand, 684; hands, 22; arm, 316; arms, 9; leg, 674; legs, 75; hand and arm, 2; hand and leg, 2; arm and leg, 5; multiple, 52; one eye, 43; both eyes, 91; hearing, 5; general disability, 54; and miscellaneous, 245.

Gases Liberated by High Voltage Insulation

Tests made by the Bureau of Mines at the plant of the Westinghouse High Voltage Insulator Company, Derry, Pa., to determine the cause of more or less frequent complaint of depression and shortness of breath on the part of new employees. The condition is most noticeable after leaving work and getting into fresh air, but the employees soon get accustomed to it and no ill effects are noticed.

The gases liberated were found to be oxides of nitrogen and ozone. The former are liberated in exceedingly small proportions—never greater than 0.2 parts per million—and the danger from these gases can be disregarded in this process as seventy-eight parts can be borne for half an hour, and only 117 to 156 parts are directly dangerous.

For ozone the maximum concentration was ten parts per million, and

then only when the samples of air were taken directly over the rack during testing and when the maximum quantity of ozone was being liberated. Samples taken on the windward side showed only two parts per million.

On the physiological effects of ozone the report gives the results of Hill and Aeberly, who found, using a test chamber, that three parts per million in normal air caused smarting of the eyes and nose, and finally a coughing spell which caused the subject to leave the chamber after ten minutes exposure. In another test a subject was able to remain for twelve minutes in the testing chamber when it contained from three to six parts per million. Jordan and Carlson found that ten parts per million for a fifteen-minute exposure caused sore throat, and that exposure for two hours to twenty parts may prove fatal.

The results of these tests indicate that no serious problem exists in the process, but continuous ventilation of the room to prevent an undue ozone concentration is recommended. This could be accomplished by placing fans directly under the testing racks to blow the gases away from the workmen. The operation of the fans for one or two minutes immediately after each test should be ample to remove the gases entirely.

New York State Laboratories

The annual report of the Division of Laboratories and Research, New York State Department of Health, for the year 1922, shows a great increase in the number of examinations of specimens. Examinations at the Albany laboratory increased 15 per cent and examinations at the New York City branch laboratory 40 per cent.

A decrease in the demand for diphtheria antitoxin has been more than offset by the increased call for Schick test outfits and for toxin-antitoxin mixture. The increase in Schick test outfits was 149 per cent, and the contained material was sufficient for 81,000 tests. The distribution of toxin-antitoxin mixture was 252 per cent greater than in the previous year.

The number of approved laboratories in the state has increased from seventy to more than 100, taxing to the utmost the ability of the staff to test the operation of each.

A new hospital and cottage building for the Kentucky Children's Home, Lyndon, Ky., is to be erected at a cost of about half a million dollars.

Peptone Solution (Armour)

5%. Isotonic—Sterile

Pituitary Liquid $\frac{1}{2}$ c c, 1 c c ampoules.

Suprarenalin Solution 1 oz. g.s. bottles.

Corpus Luteum, true substance.

Thyroids, standardized for iodine content.

Elixir of Enzymes, digestant and vehicle.

Suprarenal Cortex — powder and tablets, free from active principle.

As an aid in immunization and desensitization. Used hypodermatically in Migraine, asthma and other allergies with satisfactory results.

This Solution is prepared from a special product consisting of primary and secondary proteoses and peptone. It is free from histamin and other toxic substances.

Peptone Solution (Armour) 1 c. c. ampoules. 12 in a box.

is high at present." On page No. 66 of the "special report" of the department and from the tabulation giving county sanatorium maintenance costs we find the per capita per day to range from \$6.69 in a seventy-one bed sanatorium to \$2.44 per day in a fifty-bed sanatorium, giving an average for the six county institutions of \$4.925 per day.

In this connection it is interesting to note that the lowest per capita cost is not in the largest institution but in the smallest sanatorium of this group.

With proper standardization of physical features and of sanatorium management, there appears no good reason why the per capita cost per day should exceed three dollars, in fact, in our state the average for 1921 (which is the year covered by the Massachusetts data) was \$2.976 per capita per day.

That a large sum of money may be saved by state supervision over construction may be shown by a comparison of such costs in Minnesota and in Massachusetts. In the latter in-

stance, the six county sanatoriums vary in cost per bed from \$8,998.86 to \$1,562.25 with an average of \$4,805.55, this including the cost of site and equipment. In Minnesota, the average is approximately four thousand dollars per bed.

It is, however, the standardization of management which is made possible by state supervision which speaks the loudest in favor of its presence in state laws.

In our own state the law-makers fully intended supervision on the part of the state to be exerted as they specified that funds from the state

treasurer only became available for construction when the approval and consent of the Advisory Commission of the Minnesota Sanatorium for Consumptives⁵ had been obtained and further funds to assist in the management when "the president and executive secretary of the Advisory Commission certify that the institution has been properly conducted."

As a result of these features of our laws, sites have been selected not remote and inaccessible, buildings have been erected fireproof and well-planned. Medical service has been secured on a full time basis and by competent, well-trained men. The business and medical records have been standardized, and the environment produced for the welfare of the patient, has, we believe, attained to a degree of perfection unequalled in any state system of county sanatoriums.

This has been made possible of achievement by producing a special tuberculosis board to serve the state, a board of five physicians, broadminded, interested, and through training and experience capable of affording the state valuable service.

From our experience of exactly—(Continued on page 936)

PARALLEL RAYS PENETRATE DEEPLY

The rays of the Thermolite penetrate deeply into tissue, just as a searchlight beam penetrates space; because they are parallel.

Thermolite rays carry radiant light and heat well below the surface, thus relieving even deep seated congestion with its consequent pain, and promoting metabolism.

There is no focal spot to burn or blister—even in prolonged application.

Progressive physicians are using Thermolite in place of convective heat, such as hot water and other superficial applications, as it is more efficient and convenient, gives greater penetration, besides having the decided advantage of combination with light.

Thermolite TRADE MARK *Radiant Light and Heat* **Applicator**

will be found remarkably efficient in the treatment of

Colds	Lumbago
Eczema	Neuritis
Rheumatism	Sprains
Female Complaints	Erysipelas
and many other ills.	

Used in Government hospitals, in the clinics of such industrial organizations as Standard Oil Company, Carnegie Steel Co., Pittsburgh, Crucible Steel Co., Harrison, N. J., Walter Baker Co., Thos. G. Plant Shoe Co., Boston, Mass., and Aetna Life Insurance Co., and in private practice.

Thermolites are scientifically designed and well made. Remarkable heating effect is secured with small current consumption reducing operating costs and maintenance to a minimum.

Illustration shows No. 0670, Office Applicator, 12" diameter, with stand, at \$30.00. No. 0645, Hand Applicator, has same design, 8" diameter, without stand, at \$10.00. Folding stand for No. 0645, \$6.

Genuine Thermolites are branded—Look for the name on top of applicator. It is your guarantee of satisfaction.

First Petroleum Jelly in Medicinal Use

ALTHOUGH from the earliest recorded history crude petroleum has been used medicinally by widely scattered peoples, still the first petroleum jelly to be refined and perfected was "VASELINE" Petroleum Jelly, by Robert A. Chesebrough, in 1869. It was immediately adopted by the medical profession. As early as 1876 the London Lancet, that most famous of medical journals, endorsed it as "very valuable for medicinal practice."

"VASELINE" Jelly revolutionized the compounding of salves and ointments. Before its discovery the only known bases were animal and vegetable greases that could not be prevented from deteriorating, becoming rancid and impure. "Vaseline" Jelly is the ideal base for such compounds because being entirely mineral, it keeps indefinitely.

"VASELINE" Jelly is absolutely pure. Its process of manufacture excludes acids and alkalis and does not leave the free, irritant particles that are found in petroleum jellies refined by chemical treatments. For over half a century "Vaseline" Jelly has held first place among petroleum jellies—and it is highly esteemed by the medical profession all over the civilized world.

"VASELINE" is the trade-mark of the Chesebrough Manufacturing Company and by the use of this distinguishing term when prescribing petroleum jelly you will be assured of the original, purest and best."

Immunization by Ingestion

(Continued from page 876)

able to secure protection by subcutaneous vaccination on account of various contraindications the ingestion of bile and vaccine by these same individuals was accomplished without difficulty.

So much for the harmlessness of oral vaccination. So far as its efficacy is concerned there has not yet been sufficient time to formulate an absolutely definitive opinion. Considerable groups of people both in the civil and the military population have been vaccinated by the oral route during the course of epidemics and so far the results obtained appear to be favorable. As illustrations we may cite two epidemics of typhoid fever, one observed in the civil population in the north of France, the other in a large military school in the department of Sarthe.

The first of these outbreaks took place in 1921 in one of the devastated regions of the Pas-de-Calais. It was made the subject of a detailed report by the department inspector of hygiene, Monsieur Vaillant. The results in brief were as follows: 1,236 inhabitants were vaccinated by the oral method and 173 subcutaneously, while 600 and 650 persons remained unvaccinated. The last group of the non-vaccinated were severely tested. Twenty-nine of them contracted typhoid before the vaccinations began, twenty-one more acquired the disease after the other vaccinations commenced giving a morbidity of 7.7 per cent. Out of the 173 persons vaccinated by the subcutaneous method with the ordinary typhoid and para-typhoid triple vaccine, four were taken sick between the fifth and the twelfth day after infection (2.3 per cent). Out of 1,236 persons to whom bile vaccine was administered by mouth, five were taken sick in the days succeeding vaccination, 0.17 per cent.

The second epidemic to which we have referred above broke out in April, 1923, at the military pritanium at la Flèche, and was reported upon by the Chief Medical Officer of that establishment, Monsieur Megnin. During the six days which passed between the diagnosis of the first case and the beginning of vaccination, forty-three cases were recorded. The pupils who had remained well up to this time were divided into two groups, the more robust were vaccinated by the subcutaneous method, the undernourished and those who

presented various contraindications were vaccinated by the oral route. As was to have been expected the epidemic did not stop at once after the vaccinations and new cases of typhoid although of a mild variety occurred in both groups. It is probable that these subjects were in the incubation stage at the time of their vaccination. The definite results two months after the close of the epidemic were as follows: among the most vigorous pupils, 253 in number who had received the triple vaccine subcutaneously, 10 were taken sick in the twenty days following vaccination. Out of the 268 less robust students who received the bile vaccine by the oral method, 5 were taken sick within eleven days after vaccination.

From a consideration of all these facts we may conclude that the injection of bile vaccines is free from harmful effects even in those subjects who offer contraindications in regard to subcutaneous vaccination, and that oral vaccination is at least as efficacious if not more efficacious than that accomplished by the subcutaneous method.

Occupational Training for Deaf Mutes

The Berlin correspondent of the American Medical Association reports at some length on studies recently made by Principal Neuert of Heidelberg on the training of deaf-mutes and their choice of vocation. By far the greater proportion of deaf-mutes take up some handicraft. The males are in the main shoemakers, tailors, carpenters, goldsmiths, glass painters, book binders, saddlers, and paper hangers. Women for the most part make their living at sewing. About 25 per cent of deaf-mutes are employed at agriculture or gardening.

About 25 per cent of deaf-mutes are married, and of those married only 40 per cent are self-supporting. It is held that all deaf-mutes, irrespective of economic condition, should receive further industrial training after dismissal from special schools, and that occupational training should not be continued in an institution but should give practical training in actual jobs.

The American Chemical Society will hold its sixty-seventh annual meeting in Washington, D. C., April 21 to 25, 1924.

Sickness and Old Age Insurance for the Ministry

A movement to safeguard the ministry of Congregational churches that has been inaugurated by the National Council of Congregational Churches under a pension plan devised by skillful actuaries will provide for the entire ministry. A foundation fund of eight million dollars will provide annuity funds during periods of disability or old age. Annual dues equivalent to 6 per cent are assessed on salaries, a burden which is relieved by the assumption of part of the burden by the individual churches, or by benefits under a special fund for this purpose for men on the smaller salaries.

Hydrogen Sulphur Gas an Industrial Poison

The conclusions of Bureau of Mines investigators in the basis of experimentation with hydrogen sulphid are that this gas constitutes an industrial poison, the toxicity of which has not been fully realized. Cases of poisoning have occurred in relatively large numbers and constant vigilance is required to prevent accidents.

Acute poisoning can be produced by low concentrations of this gas, and may result in respiratory paralysis followed by heart failure and death.

Hydrogen sulphid is sometimes present in mines, railroad tunnels, and marshes. It is found in various stages of the manufacture of sulphuric acid, in the distillation of petroleum, and also about some gas wells, gas plants, and smelters.

Society of Industrial Engineers Elect

At the annual meeting of the Board of Directors of the Society of Industrial Engineers, held in November, W. G. Sheehan, of Crystal Corporation, Detroit, was elected president; Edward T. Miller, of the United Typothetae of America, treasurer; and George C. Dent, Chicago, was re-elected executive secretary. The following men were elected to existing vacancies on the board: W. W. Nichols, mechanical engineer, D. P. Brown & Co., Detroit; Frederick E. Rein, consulting industrial engineer, Philadelphia; and John F. Putnam, comptroller, Holeproof Hosiery Company, Milwaukee.

The eleventh S. I. E. convention will be held at Buffalo, N. Y., April 30, May 1 and 2.

The Management of an Infant's Diet

Malnutrition, Marasmus, Infantile Atrophy, Athrepsia

Mellin's Food
Skimmed Milk (1% fat)
Water

8 level tablespoonfuls
9 fluidounces
15 fluidounces

This mixture contains 56.61 grams of carbohydrates, thus supplying material that is utilized rapidly for heat and energy. The predominating carbohydrate is MALTOSE, which has the highest point of assimilation of any of the sugars, is immediately available as fuel and may be safely given in comparatively large amounts. The daily intake of protein from the employment of this formula is 15.54 grams, an amount calculated to be sufficient to replace depleted tissues and to provide for new growth. There is present in the mixture 4.32 grams of salts for replenishing inorganic elements.

The suggested modification furnishes nutrition in keeping with the character and amount of food elements best adapted to the particular demands of infants in an extreme state of emaciation and serves well as a starting point in attempting to meet the nutritive requirements of these undernourished babies.

Mellin's Food Co., 177 State Street Boston, Mass.

Central Purchasing for City and County

On May 17 there went into effect in San Francisco, Calif., an ordinance providing for an organization of Bureau of Supplies, which department, under the direction of a purchaser of supplies, will take care of needs of every kind of the several departments of the City Government except the Public Library.

The Purchaser of Supplies is given the authority to sign contracts for supplies for future delivery and payment, not exceeding one thousand dollars. Any contract calling for an expenditure in excess of this amount must be entered into jointly with the head of the department submitting the requisition.

The ordinance requires that all purchases made in the open market, except of patented or proprietary articles, fresh fruits and vegetables, and purchases of minor amounts, shall be based on at least three quotations. A record of these quotations and a register of all informal awards will be kept by the Bureau of Supplies.

Authority is given to the purchaser of supplies to prescribe tests for the determination of the quality of all proposed purchases or deliveries, when such quality can be accurately determined by tests. The laboratory facilities of the city, and the services of the technical staff connected with that department, are to be placed at the disposal of the Bureau of Supplies for making whatever tests are required.

The demand for training in citizen military training camps exceeded all previous years, enrollment for the summer having reached a total of 34,500 persons. The demand was smallest in the First Corps area, which is made up of the New England States.

The next annual meeting of the American Academy of Applied Dental Science will be held in Cincinnati, Ohio, January 7-9, 1924.

Memorial Number of Health News

Health News, the monthly bulletin of the New York State Department of Health for July is devoted to a series of eloquent tributes to the late Dr. H. M. Biggs by a score of the leading public health workers of the country with whom Dr. Biggs was associated in the course of his professional career.

Seek Uniform Hospital Building Code

A uniform building code for hospitals is in a fair way of being developed at the instigation of Asa S. Bacon, president of the American Hospital Association. Committee report on the investigations of hospital building codes now under way will be made by Charles H. Owsley, architect of Youngstown, O., chairman.

The National Tuberculosis Association has issued a directory listing 662 sanatoriums, hospitals, day camps, and preventorium for the treatment of tuberculosis in the United States, together with a list of government hospitals which care for the tuberculous.

Appropriation of \$15,000 for the Division of Child Hygiene assures the continuance of the present program in Minnesota under the provisions of the Sheppard-Towner law for another two years.

The plans for a nation-wide campaign for periodic health examinations are well under way in Ohio. Dr. John E. Monger, state director of health, is chairman of the Ohio committee. Organization of a local health committee is to be effected in each health district to be made up of representative civic and welfare groups, and a health week, to be designated for some time in November, is to initiate the campaign.

A survey of community health and hospitals in San Francisco is to be made at once by Dr. Haven Emerson under the auspices of the community chest and the Council of Social and Health Agencies.

Welfare in Mining Communities

The problems of housing, health and welfare work, and mining community activities generally, are to be dealt with on a national scale in the soft coal industry through the recent establishment of a department of the National Coal Association to specialize in maintaining high living standards in mining towns.

Since coal is often mined in remote places, housing and community activities in general devolve upon the employers. It is estimated that investments in miners' houses, company stores, and welfare building, including churches, moving picture theatres, gymnasiums, and similar institutions, approximate 50 per cent of a company's investment in a coal mining community.

Vital Statistics of New Zealand

The report of the Director General of Health of New Zealand for the year ending March 31, 1923 will be studied by sanitarians with keen interest in view of the remarkable results which have been achieved in that country. The crude death rate of 8.77 per 1,000 is influenced to a considerable extent by the age composition of the population, since it is increased by standardization on the basis of the international index of mortality to 10.70. The infant mortality rate of 41.9 represents, however, a remarkable achievement as does the diphtheria rate of 6.2 per 100,000 and the tuberculosis rate of 74.8. Typhoid fever went up to 5.4 as a result of a water epidemic at Mount Albert which was responsible for 30 deaths.

Pirquet Returns to Vienna

De. Clemens F. Pirquet, who came to the United States to head the department of pediatrics at the University of Minnesota, resigned and returned to Vienna after serving at his new post for a period of only two weeks.

The proprietors of agricultural lands are required by a new resolution of the Ministry of Promotion of Peru to construct houses for their workmen as a preventive against bubonic plague. Foundations and floors are to be of stone or concrete construction, rat proof. Adequate sunlight and ventilation are provided and plans are to include running water, drainage, and proper sanitary arrangements.

An International Legion for Child Welfare has been established in Brazil under the auspices of the Brazilian Women's Legion. A center of child welfare is soon to be established.

Occupational work formerly conducted at Columbia Hospital, Milwaukee, has expanded to an extent that has required its removal to a separate building on Van Buren Street where it will operate as a center where physicians in private practice, in industry, or in insurance work may send patients for reeducation and rehabilitation.

The publications sponsored by the Harrower Laboratory, Glendale, Cal., beginning with October issue, have been consolidated into one monthly, *The Endocrine Survey*.

Tycos Urinalysis Glassware

Provides for all the more important tests of the urine. It is of new design, careful workmanship and proven accuracy. Serviceable alike to the clinician and laboratory worker.

Particular attention is directed to the standard Albuminometer shown here designed for either Esbach's or Pfeiffer's method. In the latter test there is no foaming or suspension of the precipitate. All albumin precipitated with no error from changes in temperature.

Those Who Work In Busy Offices

labor under conditions which impose a constant tax on the nervous and mental forces of the body. Extreme fatigue is a natural consequence, but those who wear

O'Sullivan's Heels

have learned that in thus avoiding the nervous tension caused by the harsh impacts of hard leather heels, they can greatly reduce nerve tire and exhaustion, and as a logical result do more and better work.

It is easy to understand, therefore, why so many physicians advise O'Sullivan's Heels for those who work under nerve tiring conditions.

O'SULLIVAN RUBBER CO., Inc., New York City

Medical Inspection of Schools

(Continued from page 866)

a child should never be advised of the presence of a non-remediable defect but in the instance of the usual run of defects there appears to be no surer way of securing the child's cooperation than through explaining simply and plainly the whys and wherefores of correction.

For the purpose of the present discussion we are considering the child as a substitute factor in securing physical improvements but under no circumstances could I consider the follow-up system complete which failed to utilize the child's natural interest in himself.

(3) *The Community Physicians.*—The fact must not be lost sight of that no program of school medical inspection and correction of defects will succeed unless it bears the endorsement and enjoys the active co-operative support of the physicians serving the community. I believe that the local physician deserves the loyalty given him by his clientele and it is very certain that more than one excellent public health endeavor has failed because the players did not direct the game through the physicians to the people.

Before concluding the author wishes to sound one admonitory note. The full beneficial effects of school medical inspection, no matter how efficiently administered, will never be realized so long as children are permitted, or rather compelled, to attend school in overcrowded, ill ventilated, poorly lighted and otherwise

insanitary buildings. The director of physical education in a neighboring state tersely summed up the situation in saying that a proper system of school health supervision consisted of making children fit to go to school and schools fit for children to go to.

There is little of the original in this plan suggesting the use of the classroom teacher as the medium for preliminary screening. It is essential, however, that the practical limitations affecting the use of teachers be recognized and that no unreasonable or distorted demands be made. In any school medical inspection program, no matter how simplified, there will be need for physicians and nurses as well as for sympathetic and competent teachers. This plan is neither applicable to nor desirable for children attending city schools. My plea is for the other half of the child population of school age whose existence under rural or semi-urban conditions is after all more often determined by individual resistance than by the operation of an artificially created sanitary atmosphere such as that enjoyed by the average city dweller. Looked at from the standpoint of national welfare, one of the most important things for this country to do is to make life under rural circumstances as wholesome and safe as possible. Anything done to "keep 'em down on the farm" will return large dividends for unless this can be done the great cities of which we boast will fade as all things fade which lack a proper foundation.

County Sanatoriums

(Continued from page 930)

ten years in the Minnesota work we are convinced of the following:

(1) A state subsidy greatly stimulates counties to establish tuberculosis sanatoriums.

(2) A state subsidy granted upon approval of an authorized state board may be used to insure high type of sanatorium construction and management.

(3) A state subsidy may well be granted even when facilities for hospitalization of the tuberculous are sufficient because of beneficial influence upon the type of management.

(4) The amount of a state sub-

sidy should approximate one-half the cost of the care of a free case.

(5) A state subsidy should be paid only after approval of construction and management has been rendered by a state board or commission composed of men especially interested and experienced in matters relating to the care, treatment and hospitalization of the tuberculous.

The city of Vera Cruz has set aside fifteen blocks of land whereon workers may erect houses. The privilege is restricted to members of labor unions.

PROMETHEUS

Your Time Is Too Valuable to Waste

The Prometheus indestructible sterilizer starts sterilization quickest by test of certified engineers.

LENDs DIGNITY AND CONFIDENCE TO YOUR OFFICE.

The Same PROMETHEUS Gives INSTRUMENT and DRESSING Sterilization

A Prometheus may cost a little more initially but in the long run it will be cheaper. A Prometheus is always ready for service—repairs are practically unheard of—but can be made quickly and cheaply.

A Safe Measure of Sanitation

THE health edict "Be Clean" carries a command to every builder, buyer, health worker, manufacturer in the land for, if cleanliness is necessary, it must be made possible in every situation where the lack of hygienic standard constitutes the fundamental health hazard.

If Vitrolite is used, a glance will tell the inspecting health officer whether a safe measure of sanitation is practised in school, cafeteria, gymnasium; for Vitrolite gives early evidence of neglect in routine care, and corners of concealed accumulations do not exist as kindly harbors for deadly germs.

The dairyman, combating dirt as an industrial hazard, achieved the most outstanding modern object lesson in health when he turned live steam on his hermetically joined Vitrolite walls, thus forever fixing the sanitary requirements of his industry.

Antiquated installations are the bane of the sanitarian. Make sanitary installation attractive, and the incentive is provided to keep it clean. Make cleaning easy, and the trick of sanitary practice is turned.

The Vitrolite Company

133 W. Washington St.
CHICAGO, ILL.

VITROLITE
"Better Than Marble"

Monetary Value of Preventive Medicine

The annual report of the Metropolitan Asylums Board presents an eloquent argument for the economic aspects of preventive medicine. It holds that sanitary and hygienic considerations would have made unnecessary a large proportion of the sum of \$11,756,840 paid out in the past year in the treatment of fevers, smallpox, mental deficiency, and tuberculosis. Fevers and smallpox, accounting for more than half of this outlay, might well have been prevented, states the report. Smallpox is especially burdensome for the reason that vaccination has of late years fallen into disrepute and "conscientious objectors" can claim exemption for themselves and families.

Birth, Death, Marriage and Divorce Rates Decline in France

There have been fewer marriages, fewer deaths, fewer divorces and fewer births in France this year than last. Of all figures those for divorce show the greatest relative decline. Where in 1922 the number of couples seeking separation was 14,300, this year the figures are under 12,000.

The number of marriages was reduced by 17,000, deaths by more than 35,000, and births by 800. In the Department of the Seine, which embraces Paris, there were 2,200 more births than last year. If the death rate stays down during the whole year France may be able for the first year in many to show a fair increase in population.

Insulin Cheap Enough for All

Owing to the unselfish attitude of the discoverers of insulin in refusing all compensation for the manufacture of the product, the drug will not be subject to exploitation, but is even now in production to meet the needs of the poorest sufferers and is available at the low cost of three cents a unit. Between 25,000 and 30,000 diabetic patients are now under insulin treatment and reports of clinical success are in from all parts of the world.

A recent Ohio survey of the distribution of medical service throughout the state brought out the fact that 75 per cent of all recent medical graduates are residents of the seven large cities in the state, and that in fifty-eight counties there is a marked decline in the number of physicians for the biennium closing December 31, 1922.

Study of Child Convalescent Management

There will be published soon a study of child convalescent procedure based upon the twelve years' records of Campbell Cottages, the convalescent branch of the New York Hospital, made by Miss Hortense Kahn of Johns Hopkins University under the direction of the Sturgis Research Fund of Johns Hopkins University.

Two Hundred Million Dollars to American Charity

According to figures compiled from statistics of 129 cities by the National Information Bureau more than two hundred million dollars are devoted every year to American charity. The effort to distribute the outlay of this enormous sum brought out very clearly undesirable duplication of activities, lax management, and other factors which make for inefficiency. It emphasized still more that the public is often exploited by professional promoters who know exactly what appeal is best calculated to evoke response at the given moment. Plea is made for business-like management on the part of social agencies as well as for the limitation of public contributions to such organizations as maintain high standards.

Enlarged Field for Institute for Crippled and Disabled Men

The Institute for Crippled and Disabled men is about to embark upon a national program to promote the training and physical and mental rehabilitation of crippled persons, particularly those disabled in industrial accidents. Dr. J. C. Faries is the medical director of the institute. R. C. Branion, recently appointed national secretary, will direct the expanded program.

A course of fifteen lectures on the mental health of children is being given in Boston University School of Education by eminent experts on child health under the direction of J. Mace Andress, head of the department of psychology and child study, Boston Normal School, and with the cooperation of the Massachusetts Society for Mental Hygiene. The course will handle in a manner useful to teachers, mothers, ministers, and social workers such topics as intelligence testing, salvaging the feeble-minded, vocational guidance, the wayward child, nervousness in the light of modern psychology, and the mental health of normal children.

The Psychology of Convalescence

It is the opinion of many prominent physicians and hospital administrators that convalescing patients should leave the hospital as soon as possible, and receive the benefits of a few weeks at a health resort, before resuming commercial, professional, or social duties. The psychological benefit of this procedure is of enormous advantage to the patient.

The HOMESTEAD, Hot Springs, Va., offers an ideal service to convalescing patients who are in need of post-hospital treatment and "conditioning." At these Springs patients can receive all the medical attention that may be required. Here are provided all approved forms of Hydrotherapy, Radium Emanatorium, Inhalatorium, Solarium, Zander Institute, Diet Kitchen—in fact, every facility for recuperation that is to be found in the best of European Spas. The Calcic Carbonate, Magnesia Carbonate, and Sulphate Springs located here are all radioactive. The springs emanate from the ground at a temperature of 106 degrees.

The HOMESTEAD, in its appointments and service, will meet all expectations. The climate is unsurpassed and the mountain scenery is magnificent, with splendid opportunities for golf, horse-back riding, etc. In addition to these is the companionship of those who are in full health or on the road to recovery—in short, Hot Springs, Va., presents the right combination of psychological and physiological factors essential to speedy recovery of health and efficiency.

Hospital officials and physicians are cordially invited to correspond with our Resident Manager for more detailed information. Write for the beautiful illustrated book, "Virginia Hot Springs," and the booklets on "The Cure at Hot Springs, Va.," "A comparison of the Hydrotherapeutic Methods at Aix-Les-Bains and Virginia Hot Springs," and "The Radio-Activity of the Mineral Waters of Hot Springs, Warm Springs and Healing Springs in Hot Springs, Va." The information in these booklets will be valuable to you.

Insulin and Coffee

IN an authoritative article on the new diabetic remedy, *Insulin*, one of the procedures given to follow in diabetic coma calls for the administration of fluids, mentioning specifically "*hot, clear Coffee.*"

If there was any possibility that Coffee would prove a deterrent factor in the success of the Insulin treatment, it is unlikely that its retention in the dietary of these cases would be sanctioned, much less recommended.

Nowadays, the best case management is that which attains desired results with the least disturbance of the patient's normal

dietary and mode of living. Isn't it true that if you rule Coffee from the dietary of the patient, you may be taking away a beverage of normal diet that may have definite therapeutic value in the case?

Coffee is a mild but effective cardiac stimulant; it is an undoubted aid to sluggish peristalsis; it is a sure antidote for certain poisons, and there is no greater appetite excitant than its rich aroma.

Why not, then, take full advantage of Coffee as a therapeutic agent, and in all fairness, rule it out only in those few cases where clinical findings indicate such action?
